Information hiding based on optimization technique for

Encrypted Images

Durfi Ashraf¹, Sayiema Amin²

^{1,2} P.G. student, Department of Electronics & Communication Engineering, Adesh Institute of Engineering & Technology, Punjab, India

Abstract- With the development of latest technologies i n communication and computer networks, the importanc e and value of exchanged data over the internet or other media types are increasing. One of the fundamental issu es with sending information over the web is the 'security' threat' it postures which means that the confidential or p ersonal information can be hacked or stolen in various p erspectives. Text fusion in images is an important techno logy for image processing. We have lots of information re lated to the reports and need lots of space to store and th e proper position and name which relates that image wit h that data. Reversible data hiding is a method to embed extra message into some unsatisfactory spread media, f or example, medical or military images with a reversible way so that the original content can be accurately restor ed. Generally data hiding is utilized for communication which is secret. In this paper, a technique is proposed for reversible data hiding in encrypted images. An algorith m is proposed which will first find out the area of interes t and after that noisy pixel. BAT algorithm is used to find the coordinates of the noisy pixels and will embed text d ata on it and after that rest of the data will be fed into th e border area of the images. The research work also prov ides the knowledge about the ability of the algorithm to s ecure and protect data against attacks and its speed and efficiency in doing so.

Keywords — Graphical user Interface, Performan ce analysis, Image encryption, reversible data hidin g, separable reversible data hiding, AOI, NAOI, BAT, image recovery, Computation time.

1. INTRODUCTION

Presently in these days, applications of computer have diffu sed into each sphere of life for control of numerous sophisti cated applications. Lot of these applications is of safety criti cal, substantial, and complex. Subsequently, there must be r eliable software. In other words, software of good quality a nd also high reliability is crucial. Aside from presence of nu merous techniques for enhanced reliability, software testin g is very common and important followed methodology. Th us, testing remains the most vital part of quality assurance i n the practice of the development of software. Even though there are so many techniques are available for quality assur ance such as design reviews, formal specifications, inspectio n and checking of model exists till today. Since the software now has now an imperative part in our lives both socially a nd economically. There is pressure for professionals of soft ware to concentrate on quality issues. The software with po or quality that can bring loss of property or life is no more a dequate to society. [1]

Software testing is very expensive and labor-intensive; it re presents pretty nearly 50% of the cost of development of so ftware system. If the process of testing could be automated, the cost of software developing ought to be decreased fund amentally. Of the problems included in software testing, on e is of specific importance here; the issue of creating test da ta. Generation of test data in testing of software is the proce dure of distinguishing program input data which fulfill crite rion of selected testing. A test data generator is a device whi ch helps a programmer in generation of test data for a prog ram. There are three types of generators of test data: path wise test generators, data specification generators, and ran dom test generators. [2]

Software testing is an imperative activity in lifecycl e of software development. Organizations of software spen d significant part of their budget in activities which are relat ed to testing. Testing incorporates executing a program on a set of test cases and contrasting the actual results with the results that are expected. Testing ought to concentrate on p revention of fault. Test cases are normally derived for some artifacts of software like specifications, design or may be im plementation of the system. For testing a system, the imple mentation ought to be understood first which should be pos sible by making a suitable model of the system. A typical so urce for tests is the program code. Each time the execution of program is done, the program is tested by the user. So we need to execute the program with the particular intent of r emoving and fixing errors. With a specific end goal to locate the highest conceivable number of errors, there must be co nduction of tests systematically and test cases ought to be d esigned by utilizing restrained techniques. UML (Unified Mo deling Language) is a broadly accepted arrangement of nota tions for modeling the system which is object oriented. It ha s numerous diagrams for portraying the dynamic behavior of objects in the system. [3]

The requirement for better quality means more pre ssure for testing of software and for test engineers dealing with it. Software Testing is the procedure of executing a pro gram with the goal of discovering errors. Each code of softw are has been assessed and confirmed through activities of S oftware Quality and Assurance yet these activities definitely not sufficient. Every time the delivery of the software to the client is done, it has been tested thoroughly by the client be fore gets it to the production. In this way QA team needs to t est the software before it gets to the client. Flow of informat ion of testing is said to be as a technique of testing which in dicates the technique to choose input test cases and analyze results of test. Majority of the engineers of software would concur that testing is a crucial component of the process of quality software, and is a standout among the most costly a nd challenging activities carried out during development an d maintenance of software. The process of software testing has been depicted as a sequence of phases, steps and proce dures that bring about Quality Software Development Deliv erv to the production. Hence Testing can be depicted as a pr ocedure utilized for establishing that the software has achie ved a predetermined degree of quality regarding selected at tributes. [1]

Testing is an imperative phase development and m aintenance of the software. It is a challenging task for invest igation of unified modeling language (UML) models followi ng the information about a system is dispersed across vario us views of model. The models of UML are proposed to help to minimize the complexity of the problem, with the increm ent in complexities and sizes of product. Still, the models of UML themselves turn out to be complex and large including a numerous interactions crosswise over several objects. It i s unwieldy for producing test models such as control flow g raph from source code. This is particularly valid for large pr ograms. The UML sequence diagrams are utilized for modeli ng distinct behavior of an object through sequence graph. S uch transitions and states are discriminating to choose the i nvocations of particular operation that would be made taki ng into account the conditions emerging during the executi on of a scenario. For testing at unit level, we can get tests fr om state machine diagrams of UML, which embody the beh avioral depiction of every component. [4]

The information about system is disseminated over a various views of the model of the system, captured throu gh substantial number of diagrams. The models of UML are expected to help in reducing the complexity of the problem, with increase in complexities and sizes of the product. Still, the models of UML themselves become complex and large i nclude a large number of interactions crosswise over many objects. Many products of software are based on state. In su ch type of systems, the behavior of system is depicted by its state. In this manner, unless a system is made to accept all it s conceivable states and tested, it would not be possible to r eveal bugs based on state. Adequate testing of the system of such type of software needs satisfactory coverage of transit ions and states of the system. It is a noteworthy issue to fulf ill the requirement specification for the production of highquality software systematically. A legitimately generated te st suite may not just find the errors in the system of softwar e and additionally help in minimizing the high cost connecte d with software testing. [4]

2. AUTOMATED TESTING

Automated software testing is a procedure in which tools of software execute pre-scripted tests on an application of sof tware before it is discharged into production. The aim of au tomated testing is to simplify as much of the effort of testin g as conceivable with minimum set of scripts. If unit testing devours a huge percentage of resources of the team of quali ty assurance (QA), such as then this process may be a decen t candidate for automation. The tools of automated testing h ave the ability of executing tests, reporting results and cont rasting results with prior runs of test. Tests completed out with these tools can be repeatedly run at any time of day.

The strategy of process being utilized to execute au tomation is known as test automation framework. Various f rameworks have been implemented over many years by or ganizations of testing and commercial vendors. Automation testing with commercial off-the-shelf (COTS) or software wi th open source can be complicated, as they mostly need cus tomization. In most organizations, automation is implement ed only when it has been resolved when it has been depicte d that the program of manual testing is not fulfilling expecta tions and it is unrealistic to acquire most human testers. [5] The steps of automation process are [6]:

- 1. Test Tool selection
- 2. Define scope of automation
- 3. Planning. Design and Development
- 4. Test Execution
- 5. Maintenance

3. UML DIAGRAM

Unified Modeling Language (UML) is a standardized used ge nerally for modeling of language in the field of software eng ineering. The Unified Modeling Language incorporates a set of techniques of graphic notation to produce visual models of object-oriented software-intensive systems. The Unified Modeling Language was developed by Grady Booch, Ivar Jac obson and Jim Rumbaing at Rational Software in 1990s. It w as adopted by the Object Management Group (OMG) in 199 7, and has been overseen by this association ever since. In 2 000, the Unified Modeling Language was acknowledged by t he International Standard Organization for Standardization (ISO) as standard for Industry for modeling intensive syste ms of software. The Unified Modeling Language is becoming fastly a required skill for anyone virtually incorporated in p rojects of software. UI designers, project managers and test ers, requirement analysts, architects, software developers a nd database professionals are progressively being asked to make and use specifications which are written in UML. It cle arly gives explanation for the concepts such as enterprise ar chitecture, business modeling and objects oriented analysis. UML is now a de-facto standard for modeling of software. T here are mainly two reasons the requirement of modeling l anguage. Firstly, the model offers a blueprint for developers so they exactly know what they need to develop and for pr oject managers so that they calculate precisely the cost of gi ven project. Secondly and more significantly, UML is the bri dge between non-technical users and technical developers. [7]

The UML became popular because of the following

reasons [7]:

1. It is very flexible. It permits many distinctive types of mo deling such as Defining database architecture, Sequencing o f events and Business Process modeling event workflow.

2. Supports Methodologies which are Object-Oriented: UML supports object-oriented methodologies. UML can be utiliz ed to design both object oriented and relational models.

3. Platform-Independent: It permits architecture of softwar e to model any type of application on any operating system in any language of programming or any network.

4. The integration of different stages of SDLC through tools of UML has brought the analyst, modeler, designer, and the developers of software application closer to one another.

4. RELATED WORK

Lots of research work has been done in the area of separabl e reversible data hiding. Many efficient methods have been proposed for reversible data hiding for encrypted images. S ome important work in the area of reversible data hiding is as follows:

In reference [5], a novel approach for separable reversible d ata hiding in encrypted images is proposed. In the first stag e, owner of the matter encrypts the original image which is uncompressed by utilizing the encryption key. At that point, data hider may compress the least significant bits of the en crypted image utilizing and key of data hiding to make an in adequate space to oblige some extra information. With an e ncoded image containing additional information, if a receiv er has the key of data hiding, he can obtain the extra inform ation however he doesn't know the content of an image. If t he receiver has both the key of encryption and key of data h iding, he can obtain the extra information and also recupera te the original content with no lapse by misusing the spatial relationship in regular image when the amount of extra inform ation is not too very expansive.

In Paper [6], authors propose an authenticated and secure d iscrete reversible data hiding in cipher images manages aut hentication and security. In the first stage, owner of the con tent encodes the image which is original and uncompressed utilizing an encryption key. At that point, data hider may co mpress the least significant bits of the encrypted image utili zing and key of data hiding to make an inadequate space to oblige some extra information. With an encoded image cont aining additional information, if a receiver has the key of da ta hiding, he can obtain the extra information however he d oesn't know the content of an image. If the receiver has bot h the key of encryption and key of data hiding, he can obtai n the extra information and also recuperate the original con tent with no lapse by misusing the spatial relationship in re gular image when the amount of extra information is not to o very vast. It is additionally a downside that if the receiver has any one key as known, and afterward he can take any o ne data from the encoded information. SHA-1 algorithm is b eing utilized keeping in mind to achieve authentication.

Reference [7] explains about the technique for reversible da ta hiding in encrypted images using DCT. Reversible data hi ding is a strategy to insert extra message into some spread media with a reversible way so that the original content can be consummately restored after extraction of the message which is hidden. The extraction of data can be accomplished by analyzing the block smoothness. This paper adopts a pla n for measuring the blocks smoothness, and uses the schem e of closest match to further diminishing the rate of error of removed bits. The results of experiment reveal that the pro posed technique offers better execution over side match sys tem.

In reference [8], more consideration is paid to reversible da ta hiding in images that are encrypted, since it keeps up the amazing property that the original cover can be losslessly r ecuperated after inserted data is obtained while securing th e content of an image confidentially. All past techniques em bed information by reversibly memory space from the encr ypted images, which may be liable to few errors on extracti on of data or restoration of image. A novel strategy is propo sed in this paper by saving space of memory before encrypt ion with a conventional RDH (Reversible Data Hiding) techn ique, and accordingly it is simple for the information hider t o reversibly embed information in the image.

In paper [9], method of data hiding by adjusting histogram of medical images and dissimilarities in view of division of b lock is proposed. Reversible data hiding by utilizing method of modification of histogram considers the distinctions of t he pixels which enhance the capacity of data hiding. To imp rove the capacity of data hiding, the method of block divisio n is preferred.

5. MOTIVATION

Reversible data hiding is a procedure through which origin al image can be recuperated back losslessly after embedded message is extracted. This technique is used in law forensic s, military and medical images where no alteration of the or iginal image is permitted. The main aim of this study is to hi de the data in encrypted images. In this work, AOI (area of i nterest) is finding out and fuse the related document in the NAOI (non area of interest) of the image. The data is fused a t the borders of the images and then build the particular an d pre-defined border space. The algorithm is proposed whic h will first find out the area of interest and then noisy pixels of an image. BAT algorithm is used to find the coordinates of the noisy pixels.

The research is based on following objectives:

- 1. To Study various reversible data hiding techniques with evaluation parameters.
- 2. To study and implement BAT algorithm for generating hash key.

Volume: 03 Issue: 01 | Jan-2016

www.irjet.net

- 3. Implementing hash key for data fusion into the host image.
- Decrypting host image and data from embedded 4. image.
- 5. Evaluating various parameters for calculating the percentage of improvement.

6. PROPOSED SCHEME

Generally there are two types of techniques of data hidingseparable reversible data hiding and non-separable reversi ble data hiding. The aim of this research is to hide the data r eversibly using BAT optimization for encrypted images. In i t, area of interest is find out for particular image and then fu se the related document in the NAOI of the image. The techn ique used is to fuse data at the borders of the image and bui ld the particular and pre-defined border space. An algorith m is proposed which will first find out area of interest and t hen use BAT algorithm to find out the coordinates of the noi sy pixels and embed text data on these pixels and rest data will be fed into the border area of images.

Fig. 3 Flowchart of proposed work

7. RESULTS AND DISCUSSIONS

This section presents the simulated results of encryption, data hiding, decryption and computation time.

hello durfi

8. CONCLUSION

The main aim of this research is to implement BAT algorith m for encrypted images to hide the data. Reversible data hi ding is a procedure in which original image can be regained back without any loss and also after getting the embedded message. It hides the secret information in the digital image in such a way that just the approved individual could interp ret the secret data and restore the original image. We have used BAT algorithm for hiding data. Hence if the image is tr ansmitted, it is secured. Our proposed algorithm has shown better results than the algorithms already present for encr yption of images.
