Abstract- This paper describes the designing of rectangular Microstrip patch antenna for all different feeding technique for wireless microstrip patch antenna i.e for IMT-Advanced (4G) applications. In this paper the antenna is resonating at 2.2 GHz frequency range which is desired frequency for IMT-Advanced (4G) range. The frequency range for 4G is vary from 1710 MHz to 2690 MHz. The proposed antenna is designed by using all four types of feeding techniques (Microstrip line feed, coaxial probe feed, proximity coupled feed and aperture coupled feed) are used. From the four feeding techniques, microstrip line and coaxial probe feeds are contacting schemes whereas proximity and aperture coupled feed are non-contacting schemes. Paper gives a better understanding of design parameters of an antenna and their effect on return loss, S-Parameters, smith chart, radiation pattern, bandwidth, VSWR and resonant frequency. Finally simulation is done using design software HFSS.

Keywords- Rectangular microstrip patch antenna, S-Parameters, smith chart, radiation pattern, bandwidth, VSWR, resonant frequency, microstrip feed, coaxial probe feed, proximity coupled feed, aperture coupled feed, HFSS.

I. INTRODUCTION
Satellite communication and wireless communication has been develop rapidly in the past decades. Today world’s communication depends on wireless links. In the last few years, the development of WLAN represented one of the principal interests in the information and communication field. Thus, the current trend in commercial and government communication system has been develop low cost, minimal weight, low profile antennas that are capable of maintaining high performance over a large spectrum of frequencies. This technology trend has focused much effort into the design MPA. MPA are well suited for WLAN/WiMAX application system and having some disadvantage, like narrow bandwidth, low gain etc. Broad banding is the main problem, for solving this problem we proposed new structure for devices that require more than one frequency band of operation. Dual-band wireless phones have become popular recently because they allow using one phone in two networks that have different frequencies. Modern wireless communication system also requires low profile, light weight, high gain, ease of installation, high efficiency, simple in structure to assure reliability and mobility characteristics. Microstrip antennas satisfy such requirements. Research on microstrip antenna in 21st century aims at size reduction, increasing gain, wide bandwidth, multiple functionality and system level integration. Significant research work has been reported on increasing gain and bandwidth of microstrip antennas. Many techniques have been suggested for achieving wide bandwidth [4-5]. Main advantage of microstrip antenna includes low profile easy to fabricate (use etching and photolithography), easy to feed (proximity coupled, microstrip line, etc.) and easy to use in array of incorporate with other microstrip circuit elements [6]. In this paper four feeding techniques are compared for IMT-Advance (4G) band (1710 – 2690 MHz).

II. FEEDING TECHNIQUES
In its most basic form, a microstrip patch antenna consist of a radiating patch on one side of a dielectric substrate which has a ground plane on the other side as shown in figure 2.1. The patch is generally made of conducting material such as copper or gold and can take any possible shape. The radiating patch and the feed lines are usually photo etched on the dielectric substrate. Feeding Techniques are classified into two categories- contacting and non-contacting. The four most popular feed techniques used are the microstrip line, coaxial probe (both contacting schemes), aperture coupling and proximity coupling (both non-contacting schemes).

A. Microstrip Line Feed
Microstrip line feeding is a technique in which a conducting strip is connected directly to the edge of the microstrip patch as shown in figure 1. The width of conducting strip is smaller as compared to the patch. This type of feeding arrangement has the advantage that the feed and patch can be etched on the same substrate to provide a planar structure. However as the thickness of the dielectric substrate being used increases, surface waves and spurious feed radiation also increases, which hampers the bandwidth of the antenna. The feed radiation also leads to undesired cross polarized radiation. This method is advantageous due to its simple planar structure.
The Coaxial feed or probe feed is a very common technique used for feeding Microstrip patch antennas. The inner conductor of the coaxial connector extends through the dielectric and is soldered to the radiating patch, while the outer conductor is connected to the ground plane. The main advantage of this type of feeding scheme is that the feed can be placed at any desired location inside the patch in order to match with its input impedance. However, its major drawback is that it provides narrow bandwidth and is difficult to model since a hole has to be drilled in the substrate and the connector protrudes outside the ground plane, thus not making it completely planar for thick substrates. Also, for thicker substrates, the increased probe length makes the input impedance more inductive, leading to matching problems. It is seen above that for a thick dielectric substrate, which provides broad bandwidth, the microstrip line feed and the coaxial feed suffer from numerous disadvantages. So to reduce these types of disadvantages, we will study non-contacting schemes.

C. Proximity coupled Feed

This method uses electromagnetic coupling between the feed line and the radiating patches, printed on separate substrates [7]. Two dielectric substrates are used such that the radiating patch is on top of the upper substrate and feed line is between the two substrates. The advantage of this coupling is that it yields the largest bandwidth compared to other coupling methods, it is somewhat easy to model and has low spurious radiation. This feeding method also provides choices between two different dielectric media, one for the feed line and one for the patch to optimize the individual performances. Matching can be achieved by controlling the width-to-line ratio of the patch and length of the feed line. The major disadvantage of this feeding scheme is that it is difficult to fabricate because of the two dielectric layers which need proper alignment. Also, the overall thickness of the antenna also increases.
D. Aperture coupled feed

In this type of feed technique, the radiating patch and the microstrip feed line are separated by the ground plane. Coupling between the patch and the feed line is made through a slot or an aperture in the ground plane and variations in the coupling will depend upon the size i.e. length and width of the aperture to optimize the result for wider bandwidths and better return losses. The coupling aperture is usually centered under the patch, leading to lower cross-polarization due to symmetry of the configuration. Since the ground plane separates the patch and the feed line, spurious radiation is minimized. Aperture coupled feeding is attractive because of advantages such as no physical contact between the feed and radiator, wider bandwidths, and better isolation between antennas and the feed network. Furthermore, aperture-coupled feeding allows independent optimization of antennas and feed networks by using substrates of different thickness or permittivity.

IV. DESIGNING

A. Microstrip Line Feed

Figure 5 Design using Microstrip Line Feed

Observation from return loss at or below -10dB as shown in figure 6, 7, 8.
1. Resonant frequency = 2.04 GHz at -21.67 dB
2. Band width = f2-f1 = 2.09-1.97 = 0.12 GHz = 120 MHz
3. VSWR = 1.08
4. Impedance Matching = 57.55ohm

Figure 6 Return loss plot of MSL Feed

Figure 7 VSWR plot using Microstrip Line Feed
Figure 8 Smith chart plot using Microstrip Line Feed

B. Coaxial Probe Feed

Figure 9 Design using Coaxial Feed
Observation from return loss at or below -10dB as shown in figure 10, 11, 12.
1. Resonant frequency=2.1 GHz at -19.77 dB
2. Band width= f2-f1= 2.13-2.03= 0.10GHz = 100MHz
3. VSWR= 1.21
4. Impedance Matching = 59.05 ohm

Figure 10 Return loss plot using Coaxial Feed

Figure 11 VSWR plot using Coaxial Feed

Figure 12 Smith Chart plot using Coaxial Feed

C. Proximity coupled Feed

Figure 13 Design using Proximity Coupled Feed
Observation from return loss at or below -10dB as shown in figure 14, 15, 16.
1. Resonant frequency=2.19 GHz at -17.90 dB
2. Band width= f2-f1 = 2.26-2.13=0.13GHz=130MHz
3. VSWR = 1.08
4. Impedance Matching = 48.80 ohm
D. **Aperture coupled feed**

![Figure 17 Design using Aperture Coupled Feed](image)

Observation from return loss at or below -10dB as shown in figure 18, 19, 20.

1. Resonant frequency=2.27 GHz at -20.06dB
2. Band width= f2-f1 = 2.33-2.21=0.12GHz=120MHz
3. VSWR = 1.02
4. Impedance Matching = 51.78 ohm
different feeding technique and with various antenna parameters are presented.
