Abstract - Among all the natural disasters such as flood, earthquake, drought, tornadoes, hurricanes the least understood and the most destructive one is earthquake. Since, they cause plenty of injuries and economical losses leaving behind a series of signs of panic. Necessity to implement seismic codes in building design, the earthquakes is like wake up call. For this a better method of analysis such as static analysis, dynamic analysis and time history analysis has to be adopted for performing the structures seismic risk assessment. This dissertation work is concerned with the "Studies on Effect of Friction Dampers on the Seismic Performance of RC Multistorey Buildings" According to IS 1893 (part 1): 2002 codal provisions the structures are analyzed by Equivalent Static method, Response Spectrum method and Time History method. The modeling and analysis is done with SAP 2000 v 14 software and the results that is, seismic parameters such as Time period, Base shear, Lateral displacement and Inter storey drift are tabulated and then comparative study of structures with and without Friction dampers has been done.

Key Words: Friction dampers; Fundamental natural time period, Base shear, Lateral displacement and Storey drift.

1. INTRODUCTION

From the past few decades world has experienced numerous devastating earthquakes resulting in increased loss of life due to collapse of buildings and severe structural damage. Occurrence of these damages during earthquakes clearly demonstrate the high seismic hazards and the structures like residential buildings, life line structures, historical structures and industrial structures are need to be designed very carefully to protect from earthquakes. now a days the structural design approach using seismic response control is now widely accepted and frequently applied in civil engineering in these days much attention has been paid to the research and development of structural control techniques such as passive control system, active control system and semi-active control system giving special importance on improvement of wind and seismic response of buildings.

The passive control system doesn't need any external power supply. Active control systems need external power supply and operate based on sensors which are attached within the structures. Semi-active control systems are the combination of both the passive and active control systems which requires external power supply and they operate based on sensors attached within the structures. But if the power supply is not their then they operate based on sensors attached within the structures. But if the power supply is not their then the passive control systems control the vibration of structures. Both of these systems can be used for strong wind motion and earthquakes. The major effects have been undertaken to develop the structural control concept in to a workable technology and such devices are installed in structures.

Dampers have become more popular recently for vibration control of structures, because of their safe, effective and economical design. Under these earthquake activities buildings have known to suffer extensive damage and even total collapse. In the aim of achieving satisfactory earthquake responses of structures, there are three methods can be identified as being practical and efficient. These are structural isolation energy absorption at plastic hinges and use of mechanical devices to provide structural control.in recent times there has been interested in the use of mechanical energy absorbing devices located within the structures. These mechanical energy absorbers have been found to be quite promising and they form the focus of the present study.

These devices absorb the energy from the earthquakes, reducing the effects on the critical components of the structures. Which do not themselves support the normal loads of the structures, can be replaced leaving the building Undamped. There are types of structural control provided by the addition of mechanical devices; active and passive control. Active control need a power supply to activate the dampers and hence may be not dependable on seismic events where the power supply could be disrupted. For this reason, dampers with active control have been tested on tall buildings subjected to wind induced loading rather than the more unpredictable cyclic loading caused by earthquakes. On the other hand, passive energy dissipation systems have emerged as special devices that are incorporated within the structure to absorb a portion of the input seismic energy.by the result of these the energy dissipation demand on

e-ISSN: 2395-0056 p-ISSN: 2395-0072

primary structural members in often considerably reduced, along with the potential of the structural damage. The idea of utilizing separate passive energy dissipating dampers within a structure to absorb a large portion of the seismic energy began with the conceptual and experimental work.

2. METHODOLOGIES

In IS method of analysis is followed by using a code – IS1893 (Part 1):2002

The seismic Analysis of building connected with and without friction dampers is done by Equivalent static analysis, Response spectrum analysis.

Table 1 combinations of loads as per IS 1893-2002 & IS875(part-3)-1987.

Combination of loads	Loads factor
Equivalentstatic	1.2 (DL+LL+EQX)
method(ESM)	1.2 (DL+LL+EQY)
	1.5 (DL+EQX)
	1.5 (DL+EQY)
Response spectrum	1.2 (DL+LL+RSX)
method(RSM)	1.2 (DL+LL+RSY)
	1.5 (DL+RSX)
	1.5 (DL+RSY)

3. DETAILS OF SELECTED BUILDING

The selected building is reinforced concrete moments resisting frame building of G+3 & G+7 are taken. building plans , elevation & 3 D views building with and without the friction damper is there in below fig. seismic zone v is taken & building Type is commercial purposes.

Fig1: Plan of Selected Multi-Storey Building

Fig2: G+3 Building with & without friction damper

Fig3: G+7 Building with & without friction damper

The result obtained from different types Seismic analysis carried out namely Equivalent static analysis & Response spectrum analysis with considering the different symmetric building models. Here is the present study, the behaviour of each models are captured and results are tabulated 1ike Natural time period, base shear, displacement & storey drift in linear analysis has done.

4.1 Natural Time Period

The time period to get from the Seismic Code iS1893(part-1):2002 & Analytical result get by using SAP-2000 r given in table 1

Table -1: Codal and analytical time period for all storey

buildings

	1	1	
Building	Models	Seismic analysis	
		Codal	Analysis
G+3	Model I	0.5428	1.3534
	Model II	0.5428	0.7715
G+7	Model I	0.9129	5.6410
	Model II	0.9129	4.0910

Fig4:Profile for all Storey Buildings for Codal and Analytical Load Combination as per IS1893 (Part-I)-2000

4.2 Base Shear

The equivalent static analysis method and responses spectrum method is to find the base shear that is tabulated below. Base shear and scaling factors for all models for1.2(DL+LL+EQL) combination

Model-I: Without Friction Dampers Building and Model-II: With Friction Dampers Building

Hence base shears obtained from the equivalent static method are larger than the dynamic response spectrum method. seismic analysis of 1.2(DL+LL+EQL) combination for G+3 and G+7 storey for model I and II for static base

shear is more for same models response base shear is less compared to static base shear.

4.3 Lateral Displacement

The lateral displacement attained from equistatic method & response spectrum method, along X & Y direction are tabulated in figures.

Table 2 Lateral displacement of G+3 storey for				
ESM RSM				
Storey	Model I	Model II	Model I	Model II
4	80.4	28.6	53.2	17.1
3	71.8	23.0	47.5	13.5
2	47.6	14.9	35.1	9.0
1 19.4 5.9		5.90	17.8	4.2
0	0.0	0.0	0.0	0.0

0	0.0	0.0	0.0	0.0		

Fig8:Storey Drift of G+7 storey for seismic combination 1.2EQX & RSX

From the table and fig. it is shows that storey drift for model I drift more than model II and they vary have a roof displacement for equivalent static and response spectrum method.

5. CONCLUSIONS

In this study the focus is made on the study of seismic demands of different RC buildings i.e, low rise and medium rise buildings using different analytical techniques for the buildings situated in seismic zone v of Indian medium soil (soil type II). That the performance of building is studied in terms of time period, base shear, lateral displacements; storey drifts in linear static and linear dynamic analysis with and without friction damper building G+3 and G+7 storey models. For the G+3 and G+7 storey building with symmetrical in plan the seismic analysis carried by equivalent static method and response spectrum method. From the analysis and results obtained we can conclude the present study.

- 1. Lateral displacements due to earthquake forces reduce by providing friction dampers.
- 2. Storey drift also reduces thus shear resistance of the building increases.

- 3. Base shear of the building increases by providing friction dampers.
- 4. The effectiveness of friction dampers in controlling lateral displacements storey drifts due to earthquake force is observed in equivalent static method, response spectrum and time history analysis method.
