Abstract - Incremental sheet forming (ISF) has established its great potential to form complex three-dimensional parts without using a matching die. The process locally deforms sheet metal using a moving tool head attaining higher forming limits than those of conventional sheet metal stamping process. The die-less nature in incremental forming provides a viable substitute for economical and effective fabricating low-volume functional sheet products. Various application areas include aerospace engineering, customized products in biomedical engineering and prototyping in the automotive engineering. This paper presents a review on experimental investigation of ISF process factors or parameters like feed rate, speed, tool diameter, sheet thickness, lubrication, step size and tool path affecting surface roughness and thickness reduction.

Key Words: Incremental sheet forming (ISF), single point incremental sheet forming, roughness, thickness reduction, tool path.

1. INTRODUCTION

Incremental Sheet Forming (ISF) process is sustainable in small scale production to deal with the various needs like customization, low tooling cost and setup time. The conventional forming processes already used in the industry (like deep drawing, stamping) need high investment cost and long die-preparation times for small scale production [1]. Therefore, ISF is a process which is, now a days, available for small batch production or prototyping as it deals with the issues in the conventional forming process.

ISF is a forming technique of sheet metal process based on layered manufacturing principle. The sheet part is locally deformed through horizontal slices. The moving locus of forming tool (tool path) in these slices is performed by the CNC milling machine. The tool path is generated directly from CAD model of final product by using CAM system. Surface roughness is reduced to increase the surface quality of parts (e.g. reflexive surfaces for headlights) and to reduce friction between mating parts like production dies and mould surfaces etc. Thickness reduction defines both Geometrical accuracy as well as the strength of the forming parts. Uniform thickness distribution leads to better geometrical accuracy and better strength.

Fig -1: Principle of Incremental Sheet Forming [1]

1.1 Classification of Incremental Sheet Forming

The ISF can be classified as

- Single Point Incremental Forming (SPIF)
- Two Point Incremental Forming (TPIF)

1.1.1 Single Point Incremental Forming (SPIF)

In SPIF type of incremental forming, the blank is clamped along its edges and the tool (generally a spherical tool) moves along the sheet surface, as shown in fig - 2. Hence no die is used and even asymmetrical parts can be easily formed. This method can be executed using a conventional CNC milling machine, including a CAD/CAM system to produce the tool path [2].

Fig -2: Single Point Incremental Sheet Forming [2]

1.1.2 Two Points Incremental Forming:

In Two Point Incremental Forming (TPIF) the blank is clamped in the blank holder which can be adjusted in the Z axis. The forming tool is similar to the tool in SPIF and performs a trajectory of the outer surface of the part, from top to bottom of the geometry. In TPIF a die is used below the blank & die has the same function as the supporting plate only and increase the geometry accuracy.

Fig -3: Two Point Incremental Sheet Forming [3]

1.2 CAM factors / process parameters used for Incremental Sheet Forming are :

- (i) Tool diameter
- (ii) Step size
- (iii) Feed rate
- (iv) Speed
- (v) Sheet Thickness
- (vi) Lubrication
- (vii) Tool path

In ISF the process parameters (like speed, feed rate, incremental step size, lubrication, tool diameter, sheet thickness, material, and tool path) are affecting the surface roughness, and thickness reduction as described below from the previous study:

Surface roughness:

Factors have greatly influenced the surface quality in incremental sheet forming. J. Kopac, Z. Kampus (2005) [6] presented the processes controlled by CNC milling machine tool with CAD/CAM. Surface roughness of aluminum sheet is lower than steel because steel is highly deformable and subjected at minimum hardening. I. Cerro, E. Maidagan (2006) [7] stated that roughness is lower in the tool advancing direction than in perpendicular one. Roughness can be decrease by decreasing axial step size.

Thickness reduction:

Factors mainly affecting thickness reduction are sheet thickness, step size and feed rate. Ambrogio et al. (2005) [5] and Young and Jeswiet (2004) [4] found that wall thickness initially greater than the sine low thickness then reduces to less than the sine low thickness across the formed region of copper plates. This suggests that thinning beyond the sine low prediction as a result of material being pushed towards the center of geometry.

2. EXPERIMENTAL SETUP

2.1 CNC Machine: All the experiments were performed at CTR (central tool room) Ludhiana, Punjab. Where precise machines are available and CNC Milling Machine is readily available. CNC Vertical Milling Machine (VMC2216XV) used for the experimentation purpose of ISF As shown in Fig -4(a)

Fig -4(a): Overview of CNC milling machine (VMC) and Fig -4(b): Stainless steel tool of diameter 20 mm

2.2 Forming Tool: Forming tool used are basically are made of hardened stainless steel. Tool diameter is 16mm, 18mm and 20mm. Tool with tool holder shown in fig -4(b).

2.3 Fixture and Clamping system for SPIF: Single point incremental sheet forming performed on hollow fixture as shown in figure. A static frame is composed with using clamping devices. Assembly drawing for the SPIF clamping system and its overview is shown in the fig - 5. A blank holder is fixed with fixture using bolts, to holds the sheet over the blank. Total working area of the machine is 240 x 240 mm² in this process

Fig -5 Assembly drawing for the SPIF Clamping System

2.4 Material used: Aluminium grade Al-2014 is used for forming process with three different thicknesses 1.2, 2 and 2.3 mm. Specification of material is described in table 1

Table 1 Material Specification:

| | |
|-----------------|----------|
| Aluminum | Balance |
| Chromium | 0.1 max |
| Copper | 3.9-5 |
| Iron | 0.7 max |
| Magnesium | 0.2-0.8 |
| Manganese | 0.4-1.2 |
| Silicon | 0.5-1.2 |
| Titanium | 0.15 max |
| Titanium + Zinc | 0.2 max |
| Zinc | 0.25 max |

2.5 Dynamometer: It is used for measuring the force during the forming process. A load cell up to 1000 kg is used for measuring the force applied by the tool on sheet during forming. Dynamometer is directly connected with fixture which holds the sheet as shown in Fig -6.

Fig - 6: Overview of Dynamometer

2.6 Lubricants: In this work, coolant, oil and grease are used as lubricants. WD-40 is used as oil and water-iscible fluid including soluble oil is used as coolant. Lubrication system used during ISF shown in fig - 7.

Fig -7: Lubrication system used during ISF

2.7 Actual experiment:

Actual experiments were conducted by varying all the process parameters using orthogonal array to study their effects on forming results. The forming results are surface roughness, thickness reduction and force based failure. All the responses are measured using different instruments. The formed parts of actual experiments are shown in Fig-8

Fig -8: Picture representation of all eighteen experiments

2.8 Instrument Used:

Surface Roughness Tester: Instrument used in this work for measurement of surface Roughness is Mitutoyo SurfTest SJ-201P as shown in fig-9 The surfTest SJ-201P (Mitutoyo) is a shop-floor type surface-roughness measuring instrument, which traces the surface various machine parts and calculates the surface roughness based on roughness standards, and displays the results.

Fig -9 Mitutoyo SurfTest SJ-201P (Surface Roughness Tester)

The work piece is attached to the detector unit of the SJ-201P will trace the minute irregularities of the work piece surface. The vertical stylus displacement during the trace is processed of the SJ-201P as shown in figure 10

Fig 10: SJ-201P surface roughness testing of formed part

3. Experimental Design Strategy

In this work, Taguchi method is used to select number of experiments and to investigate the effects of process parameters on the responses like surface roughness, thickness reduction and forming force. Seven parameters viz. tool path, tool diameter, sheet thickness, step size, spindle

speed, feed rate and lubrication are considered and represented at different levels.

In the Taguchi method, the results of the experiments are analyzed to achieve one or more of the following objectives:

- To estimate the best or the optimum condition for a product or process.
 - To estimate the contribution of individual parameters and interactions.
 - To estimate the response under the optimum condition.
- The optimum condition is identified by studying the main effects of each of the parameters. The analysis of variance (ANOVA) is the statistical treatment most commonly applied to the results of the experiments in determining the percent contribution of each parameter against a stated level of confidence.

4. RESULT AND DISCUSSION

4.1 Experimental Results:

Experiments of SPIF were performed on the basis of selected orthogonal arrays (L18) for studying the effect of parameters whose values are assigned in table 2. In the present work all the experimental results are obtained using Minitab 17 Statistical software.

Table 2: Taguchi L18 Orthogonal Arrays with response mean and S/N ratio

| Tri al No. | To ol path | To ol Diame ter (mm) | Sheet thickn ess (mm) | Ste p Size (m m) | Spind le Spee d (rpm) | Feed Rate (mm/ min) | Lubr i- catio n | Response (Raw data) | | S/N Rati o |
|------------|------------|----------------------|-----------------------|------------------|-----------------------|---------------------|-----------------|---------------------|----------------|------------|
| | | | | | | | | R ₁ | R ₂ | |
| 1. | 1 | 1 | 1 | 1 | 1 | 1 | 1 | - | - | - |
| 2. | 1 | 1 | 2 | 2 | 2 | 2 | 2 | - | - | - |
| 3. | 1 | 1 | 3 | 3 | 3 | 3 | 3 | - | - | - |
| 4. | 1 | 2 | 1 | 1 | 2 | 2 | 3 | - | - | - |
| 5. | 1 | 2 | 2 | 2 | 3 | 3 | 1 | - | - | - |
| 6. | 1 | 2 | 3 | 3 | 1 | 1 | 2 | - | - | - |
| 7. | 1 | 3 | 1 | 2 | 1 | 3 | 2 | - | - | - |
| 8. | 1 | 3 | 2 | 3 | 2 | 1 | 3 | - | - | - |
| 9. | 2 | 3 | 3 | 1 | 3 | 2 | 1 | - | - | - |
| 10. | 2 | 1 | 1 | 3 | 3 | 2 | 2 | - | - | - |
| 11. | 2 | 1 | 2 | 1 | 1 | 3 | 3 | - | - | - |
| 12. | 2 | 1 | 3 | 2 | 2 | 1 | 1 | - | - | - |
| 13. | 2 | 2 | 1 | 2 | 3 | 1 | 3 | - | - | - |
| 14. | 2 | 2 | 2 | 3 | 1 | 2 | 1 | - | - | - |
| 15. | 2 | 2 | 3 | 1 | 2 | 3 | 2 | - | - | - |
| 16. | 2 | 3 | 1 | 3 | 2 | 3 | 1 | - | - | - |
| 17. | 2 | 3 | 2 | 1 | 3 | 1 | 2 | - | - | - |
| 18. | 2 | 3 | 3 | 2 | 1 | 2 | 3 | - | - | - |

R1 and R2 are repeated values of response. Where 1, 2 and 3 represent the values of 1st, 2nd and 3rd level for each factor respectively.

4.2 Analysis and discussion of result:

All the SPIF experiments are conducted using the parametric approach of Taguchi method to measure the effects of individual process parameters on the response. The mean and S/N ratio data for different level are calculated from experimental results and then the effects of process parameters for both mean and S/N ratio data are plotted. The response curves are used for examine the effect of parameters on the response characteristics. The analysis of variance (ANOVA) of mean and S/N ratio data is used to categorize the significant variable and to measure their effects on the response characteristics. The optimum value of process variables in terms of mean are established by analysing response curve and ANOVA table.

4.2.1 Effect on Surface Roughness:

The effects of process parameters on Surface roughness of formed part is calculated by using mean and S/N ratio of each row where Surface roughness for each level of experiment is established in orthogonal array. Orthogonal array with mean and S/N ratio data is shown in table 3.

Table 3 Orthogonal array for result of Surface roughness with mean & S/N ratio data

| Tri al No. | To ol path | To ol Diame ter (mm) | Sheet thickn ess (mm) | Ste p Size (m m) | Spind le Spee d (rpm) | Feed Rate (m m/ min) | Lubr i- catio n | Surface Roughne ss (µm) | | Mean | S/N Ratio |

Selection of optimal levels:

Effect of process parameters over surface roughness is calculated by using response tables. The response table 4 and 5 shows the average of each surface roughness characteristic of each level for every factor. Surface roughness “smaller is better” type quality characteristic. From chart-1 it found that second level of tool path (A2), second level of tool diameter (B2), first level of sheet thickness (C1), third level of step size (D3), second level of spindle speed (E2), first level of feed rate (F1) and second level of lubrication (G2) are optimum values. S/N ratio and Mean data of surface roughness for each corresponding level is shown in table 4 and 5.

Table 4 Response table for S/N ratio of Surface Roughness (Smaller is better)

| Level | Tool Path | Tool Dia. | Sheet Thickness | Step Size | Spindle Speed | Feed rate | Lubrication |
|-------|-----------|-----------|-----------------|-----------|---------------|-----------|-------------|
| 1 | 1.09401 | 1.07943 | 1.02483 | 0.63041 | 2.85030 | 0.17859 | -1.00332 |

| Delta | 0.62826 | 0.75257 | 3.96023 | 0.33579 | 3.29468 | 1.04981 | 0.65903 |
| Rank | 6 | 4 | 1 | 7 | 2 | 3 | 5 |

Table 5 Response table for Mean of Surface Roughness (Smaller is better)

| Level | Tool Path | Tool Diameter | Sheet Thickness | Step Size | Spindle Speed | Feed rate | Lubrication |
|-------|-----------|---------------|-----------------|-----------|---------------|-----------|-------------|
| 1 | 1.1614 | 1.1537 | 0.9321 | 1.1221 | 1.4371 | 1.0638 | 1.1513 |
| 2 | 1.1411 | 1.0883 | 1.0700 | 1.2150 | 0.9858 | 1.2075 | 1.0675 |
| 3 | | 1.2117 | 1.4517 | 1.1167 | 1.0308 | 1.1825 | 1.2350 |
| Delta | 0.0203 | 0.1233 | 0.5196 | 0.0983 | 0.4512 | 0.1437 | 0.1675 |
| Rank | 7 | 5 | 1 | 6 | 2 | 4 | 3 |

Main effect plots for S/N ratio and Mean data are shown in chart 1 and 2 respectively, to predict the effect of process parameters for different levels on the surface roughness for same factor.

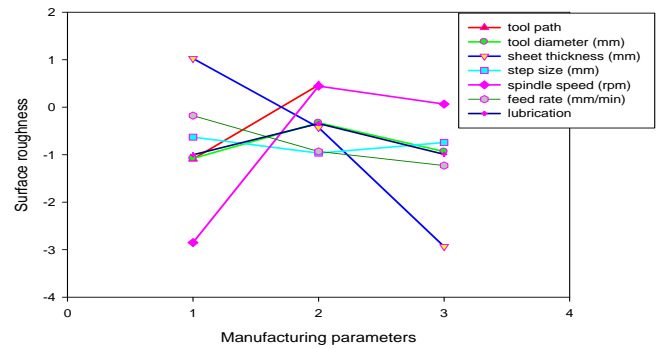

Chart-1 Effect of plot for S/N ratio (for Surface roughness)

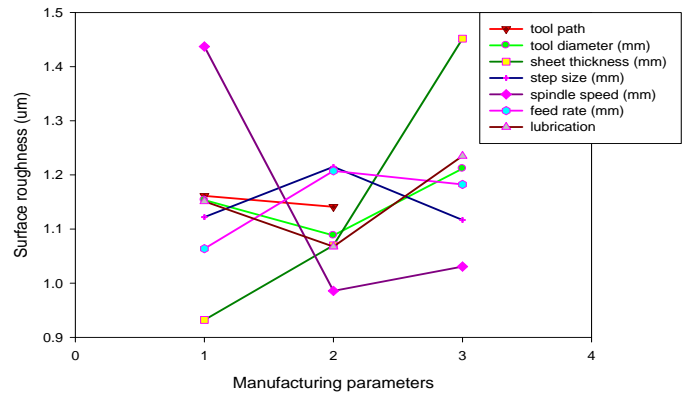

Chart-2 Effect of plot for Mean (for Surface roughness)

Analysis of variance for Surface Roughness (SR):

To study the significance of process parameters over Surface roughness analysis of variance (ANOVA) is performed in design of experiment. For 95% confidence level value of P should be less than 0.05. Therefore, from table it is clearly signified that all the process parameters affects the surface roughness. As Surface roughness “smaller is better” type quality characteristic. So, smaller value of surface roughness is considered as optimal. The raw data of ANOVA is given in table 6 using MINITAB17.

Table 6 Analysis of Variance for SR, using Adjusted SS (for Surface roughness)

| Source | DF | Adj SS | Adj MS | F | P |
|---------------|----|---------|----------|-------|-------|
| Tool Path | 1 | 0.00370 | 0.003701 | 0.05 | 0.831 |
| Tool Dia. | 2 | 0.09138 | 0.045690 | 0.57 | 0.572 |
| Sheet Thk. | 2 | 1.73863 | 0.869315 | 10.92 | 0.001 |
| Step Size | 2 | 0.07333 | 0.036665 | 0.46 | 0.637 |
| Spindle Speed | 2 | 1.48276 | 0.741381 | 9.31 | 0.001 |
| Feed Rate | 2 | 0.14156 | 0.070781 | 0.89 | 0.425 |
| Lubrication | 2 | 0.16834 | 0.084169 | 1.06 | 0.364 |
| Error | 22 | 1.75187 | 0.079630 | | |
| Total | 35 | 5.45157 | | | |

S = 0.282189, R-sq = 67.86%, R-sq(adj) = 48.88%& R-sq(pred)= 13.95% R-sq(pred)= 13.95%

Most influential factor for Surface roughness can be decided using rank. According to the ascending order of rank, value the most effective process parameter is sheet thickness followed by spindle speed, lubrication, feed rate, tool diameter, step size and tool path. Thus optimum values can easily find out for better surface roughness.

4.5.2 Effect on Thickness Reduction:

In order to see the effect of process parameters on thickness reduction we used the orthogonal array as shown in table 7 with Mean and S/N ratio data.

Table 7 Orthogonal array for Thickness reduction with Mean and S/N ratio data

| S. N. | Tool Path | Tool Dia. (mm) | Sheet thickness (mm) | Step Size (mm) | Spindle Speed (rpm) | Feed Rate (mm) | Lubrication | Thickness reduction %/30mm | | Mean | S/N Ratio |

Selection of optimal levels:

Using the response table 8 and 9, selection of optimum parameters has been made and the effect of process parameters over thickness reduction is calculated. Thickness reduction is also a “smaller is better” type quality characteristic. Therefore, from figure 4.4 it is found that first level of tool path (A1), third level of tool diameter (B3), second level of sheet thickness (C2), third level of step size (D3), third level of spindle speed (E3), first level of feed rate (F1) and third level of lubrication (G3) are optimum values. Table 8 and 9 shows the S/N ratio and Mean data of thickness reduction for each corresponding level.

Table 8 Response table for S/N ratio of Thickness reduction (Smaller is better)

| Level | Tool Path | Tool Dia. | Sheet Thickness | Step Size | Spindle Speed | Feed rate | Lubrication |
|-------|-----------|-----------|-----------------|-----------|---------------|-----------|-------------|
| 1 | -30.63 | -32.09 | -32.58 | -30.73 | -31.98 | -28.67 | -31.17 |
| 2 | -31.48 | -31.77 | -29.66 | -31.75 | -31.45 | -32.77 | -31.21 |
| 3 | - | -29.31 | -30.93 | -30.69 | -29.73 | -31.74 | -30.79 |
| Delta | 0.85 | 2.79 | 2.92 | 1.05 | 2.25 | 4.10 | 0.42 |
| Rank | 6 | 3 | 2 | 5 | 4 | 1 | 7 |

Table 9 Response table for Mean of Thickness reduction (Smaller is better)

| Level | Tool Path | Tool Diameter | Sheet Thickness | Step Size | Spindle Speed | Feed rate | Lubrication |
|-------|-----------|---------------|-----------------|-----------|---------------|-----------|-------------|
| 1 | 35.53 | 40.71 | 42.65 | 36.43 | 40.04 | 28.67 | 36.77 |
| 2 | 39.04 | 39.56 | 33.56 | 39.30 | 39.63 | 44.13 | 38.87 |
| 3 | - | 31.58 | 35.65 | 36.13 | 32.19 | 39.05 | 36.22 |
| Delta | 3.51 | 9.14 | 9.09 | 3.17 | 7.85 | 15.46 | 2.64 |
| Rank | 5 | 2 | 3 | 6 | 4 | 1 | 7 |

The effect of process parameters on thickness reduction for different level and same factor using S/N ratio and Mean data are plotted in chart 3 and 4.

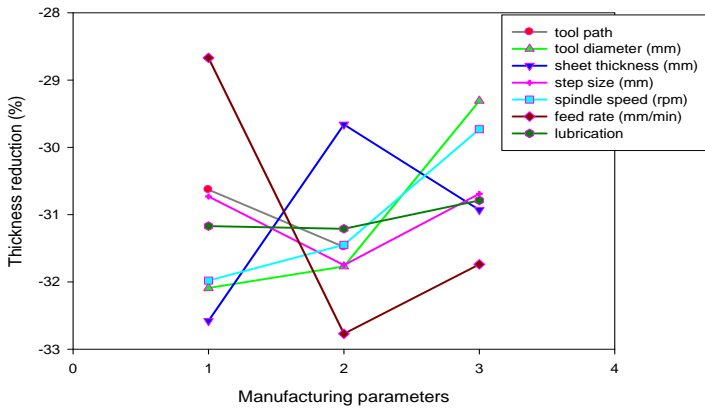

Chart -3 Effect of plot for S/N ratio (for thickness reduction)

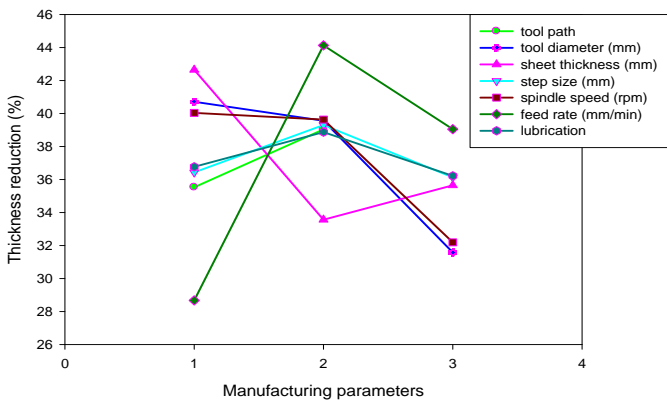

Chart -4 Effect of plot for Mean (for Thickness reduction)

Analysis of variance for Thickness Reduction (TR):

From table 10, it is clearly signified that all the process parameters affects the thickness reduction because for 95% confidence level value of P should be less than 0.05. Thickness reduction “lower is better” type quality characteristic. So, smaller value of thickness reduction is considered as optimal.

Table 10 Analysis of Variance for TR, using Adjusted SS (for Thickness reduction)

| Source | DF | Adj SS | Adj MS | F | P |
|-------------|----|---------|---------|-------|-------|
| Tool Path | 1 | 110.81 | 110.811 | 7.71 | 0.011 |
| Tool Dia. | 2 | 594.33 | 297.165 | 20.66 | 0.000 |
| Sheet Thk. | 2 | 544.12 | 272.062 | 18.92 | 0.000 |
| Step Size | 2 | 73.35 | 36.675 | 2.55 | 0.101 |
| Spindle | 2 | 468.72 | 234.359 | 16.30 | 0.000 |
| Feed Rate | 2 | 1490.05 | 745.023 | 51.81 | 0.000 |
| Lubrication | 2 | 46.76 | 23.380 | 1.63 | 0.220 |
| Error | 22 | 31.638 | 1.4381 | | |
| Total | 35 | 3644.51 | | | |

$S = 3.79219, R\text{-sq} = 91.32\%, R\text{-sq(adj)} = 86.19\% \& R\text{-sq(pred)} = 76.76\%$

According to ascending order of rank value the most effective process parameter is lower value of rank. Therefore, most effective parameter in case of thickness reduction is feed rate followed by tool diameter, sheet thickness, spindle speed, tool path, step size and lubrication. Thus optimum values can easily find out for better thickness reduction.

4.5.3 Effect on forming Force:

To predict the effect of process parameters on forming force using Mean and S/N ratio data. Mean and S/N ratio data of forming force with its orthogonal array is shown in table 11.

Table 11 Orthogonal array for forming Force with Mean and S/N ratio data

| Trial No. | Tool path | Tool Dia (mm) | Sheet thickness (mm) | Step Size (mm) | Spindle Speed (rpm) | Feed Rate (mm/min) | Lubrication | Forming Force (N) | Mean | S/N Ratio |
|-----------|-----------|---------------|----------------------|----------------|---------------------|--------------------|-------------|-------------------|----------------|----------------|
| | | | | | | | | R ₁ | M ₁ | S ₁ |
| 1 | Spiral | 16 | 1.2 | 0.3 | 0 | 1500 | Coolant | 1751.26 | 1751.26 | 64.867 |
| 2 | Spiral | 16 | 2 | 0.5 | 10 | 2000 | Oil | 2058 | 2058 | 66.2689 |

| 9 | Spiral | 20 | 2.3 | 0.3 | 20 | 2000 | Coolant | 7350 | 7350 | 77.3257 |
| 10 | Helical | 16 | 1.2 | 0.7 | 20 | 2000 | Oil | 1156.4 | 1156.4 | 61.2622 |
| 11 | Helical | 16 | 2 | 0.3 | 0 | 3000 | Grease | 4057.2 | 4057.2 | 72.1645 |
| 12 | Helical | 16 | 2.3 | 0.5 | 10 | 1500 | Coolant | 5635 | 5635 | 75.0179 |
| 13 | Helical | 18 | 1.2 | 0.5 | 0 | 1500 | Grease | 1185.8 | 1185.8 | 61.4802 |
| 14 | Helical | 18 | 2 | 0.7 | 0 | 2000 | Coolant | 2077.6 | 2077.6 | 66.3 |

| | | | | | | | | | | |
|----|---------|----|-----|------|----|-----|---------|--------|--------|---------|
| | | | | | | | | | | 512 |
| 15 | Helical | 18 | 2.3 | 0.3 | 10 | 300 | Oil | 6076 | 6076 | 75.6 |
| 16 | Helical | 20 | 1.2 | 0.75 | 10 | 300 | Coolant | 1342.6 | 1342.6 | 62.5589 |
| 17 | Helical | 20 | 2 | 0.3 | 20 | 150 | Oil | 5450.6 | 5450.6 | 75.344 |
| 18 | Helical | 20 | 2.3 | 0.5 | 0 | 200 | Grease | 6310 | 6310 | 76.0828 |

Selection of optimal levels:

Selection of optimum parameters and the effect of process parameters over forming force are calculated by using response table 12 and 13. As the forming force “smaller is better” type quality characteristic, it is found that second level of tool path (A2), first level of tool diameter (B1), first level of sheet thickness (C1), second level of step size (D2), second level of spindle speed (E2), second level of feed rate (F2) and second level of lubrication (G2) are optimum values of forming force to minimize the forming force during manufacturing process.

Table 12 Response table for S/N ratio of forming Force (Smaller is better)

| Level | Tool Path | Tool Diameter | Sheet Thickness | Step | Spindle | Feed rate | Lubrication |
|-------|-----------|---------------|-----------------|-------|---------|-----------|-------------|
| 1 | -70.3 | -69.19 | -62.18 | -71.0 | -69.75 | -71.3 | -70.14 |
| 2 | -69.5 | -69.40 | -71.54 | -69.2 | -69.16 | -68.0 | -69.60 |
| 3 | -71.27 | -71.27 | -76.14 | -69.5 | -70.95 | -70.4 | -70.13 |
| Delta | 0.81 | 2.08 | 13.95 | 1.83 | 1.79 | 3.33 | 0.54 |
| Rank | 6 | 3 | 1 | 4 | 5 | 2 | 7 |

Table 13 Response table for S/N ratio of forming Force (Smaller is better)

| Level | Tool | Tool | Sheet | Step | Spindle | Fee | Lubrication |
|-------|------|------|-------|------|---------|------|-------------|
| 1 | 416 | 3444 | 1301 | 436 | 3784 | 448 | 3933 |
| 2 | 375 | 3851 | 4124 | 365 | 3584 | 335 | 3931 |
| 3 | 4570 | 6440 | 384 | 4498 | 402 | 4002 | |
| Delta | 410 | 1126 | 5139 | 713 | 915 | 112 | 70 |
| Rank | 6 | 2 | 1 | 5 | 4 | 3 | 7 |

Main effect plot for S/N ratio and Mean data are shown in chart 5 and 6 respectively.

Chart -5 Main effect plot for S/N ratio (forming Force)

Chart -6 Main effect plot for Mean (forming Force)

5. CONCLUSIONS

1. Sheet thickness is most influential process parameter on surface roughness followed by spindle speed and lubrication where feed rate, tool diameter, step size and tool path have little influence over surface roughness. The optimal experimental condition are determined as tool path (helical), tool diameter (18mm), sheet thickness (1.2mm), step size (0.75mm), spindle speed (100rpm), feed rate (1500mm/min) and lubrication (oil) with minimum surface roughness (0.64µm), which is efficiently confirmed by validation experiment.
2. Feed rate is highly influential factors in case of thickness reduction followed by tool diameter, sheet thickness, spindle speed but tool path, step size and lubrication have little influence on thickness reduction. The optimal experimental condition for thickness reduction are determined as tool path (spiral), tool diameter (20mm), sheet thickness (2mm), step size (0.75mm), spindle speed (200rpm), feed rate (1500mm/min) and lubrication (grease) with minimum thickness reduction (14.83%).
3. Most influential process parameter on forming force is sheet thickness followed by tool diameter, spindle speed, feed rate, step size while tool path and lubrication little influence on forming force. The optimal experimental condition for forming force are determined as tool path (helical), tool diameter (16mm), sheet thickness (1.2mm), step size (0.5mm), spindle speed (100rpm), feed rate (2000mm/min) and lubrication (oil) with minimum forming force (1,127N).

4. Al-2014 is high strength and hardness alloy, hence large amount of forming force (7350 N) is calculated during ISF, which cause of abrupt failure in case of thick sheet. So, it is estimated that low hardness and thin sheet have good formability for ISF.

5. For overall performance including surface quality, thickness distribution and forming force, sheet thickness is most influential process parameter in ISF and for better quality product it should be used between 1.2mm to 2mm.
