Evapotranspiration Studies for Jhabua District

Shardool Singh¹, Mayank Soni², Pratish Awasthi³ Manish Pandey⁴

¹²³⁴ Assistant Professor, Department of Civil Engineering, CDGI, MP, India

Abstract - To plan a proper & feasible irrigation scheme, the knowledge of exact amount of water required by different crops under different climatic condition is necessary. Accurate and exact estimation of crop evapotranspiration is very helpful in the effective design of an irrigation system.

In this research work the observations were recorded for Jhabua district of Madhya Pradesh state. These observation were used to calculate the evapotranspiration by using FAO-56 Method, Turc method and Makkink method. The results of each method are compared with the result of FAO-56 method.

Key Words: Evapotranspiration, Jhabua District, FAO-56, Turc, Makkink, Irrigation.

1. INTRODUCTION

India, with a geographical area of about 329 Million Hectares (Mha), is a land of many mountains and rivers, some of them figuring amongst the mightiest rivers of the world. Physiographically, India may be divided into seven well defined regions. These are: the Northern Mountains comprising the mighty Himalayan ranges; the Great Plains traversed by the Indus, Ganga and Brahmaputra river systems; the Central Highlands, consisting of a wide belt of hills running east-west between the Great Plains and the Deccan plateau; the Peninsular Plateaus; the East Coast, a belt of land of about 100-130 km wide, bordering the Bay of Bengal; the West Coast, a narrow belt of land of about 10-25 km wide, bordering the Arabian Sea; and the islands, comprising the coral islands of Lakshadweep in Arabian Sea and Andaman and Nicobar group of islands in the Bay of Bengal.

Water resources are sources of water that are useful or potentially useful to humans. It is basic human need and a prime national asset. It is important because it is needed for life to exist. Water is a natural resource serving a wide range of uses in modern day society. Beside the basic purpose for support of life, water is also used for other purposes such as Agricultural, industrial, household, recreational, environmental activities, irrigation, hydropower, navigation, pollution abatement etc. Irrigation is the only use of water discussed herein. It is estimated that 70% of world-wide water use is for irrigation in agriculture.

Vast area of India is under tropical climate which is conducive throughout the year for agriculture due to favorable warm and sunny conditions provided perennial water supply is available to cater to the high rate of evapotranspiration from the cultivated land. The availability of water distribution are governed by climatic factors beyond man’s control, at the present state of science and technology. Instead of opting for centralized mega water transfer projects which would take long time to give results, it would be cheaper alternative to deploy extensively shade nets over the cultivated lands for using the locally available water sources efficiently to crops throughout the year. Plants need less than 2% of total water for metabolism requirements and rest 98% is for cooling purpose through transpiration. Shade nets or poly-tunnels installed over the agriculture lands suitable for all weather conditions would reduce the potential evaporation drastically by reflecting the excessive and harmful sun light without falling on the cropped area. Optional management of water resources is therefore fundamental in ensuring the continuous availability of water for the benefit of mankind both for the present and the future. The natural availability water is often not sufficient to satisfy the demand and use imposed by society. Control of water has therefore been practiced since the early days of civilization.

The main objective and aim of water resources planning and management is to solve the equation of demand and supply of water for a specific area taking into account considering various dimensions like space, time, economy, politics, environment, and other aspects. An objective of irrigation planners is to obtain a high level of economic efficiency in irrigation development and in water system use. There is an increasing awareness observed in recent times to make the best use of water, a scarce and valuable resource for all economic activities.

1.1 EVAPO-Transpiration Process

The crop water need (ET crop) is defined as the depth (or amount) of water needed to meet the water loss through evapotranspiration. In other words, it is the amount of water needed by the various crops to grow optimally. The crop water need always refers to a crop grown under optimal conditions, i.e. a uniform crop, actively growing, completely shading the ground, free of diseases, and favorable soil conditions (including fertility and water). The crop thus reaches its full production potential under the given environment. The crop water need mainly depends on: - The climate: in a sunny and hot climate crops need more water per day than in a cloudy and cool climate. - The crop type: crops like maize or sugarcane need more water than crops like millet or sorghum. - The growth stage of the crop: fully grown crops need more water than crops that have just been planted.
1.1.1 Evaporation:

Evaporation is the process whereby liquid water is converted to water vapor (vaporization) and removed from the evaporating surface (vapor removal). Water evaporates from a variety of surfaces, such as lakes, rivers, pavements, soils and wet vegetation.

1.1.2. Transpiration:

Transpiration consists of the vaporization of liquid water contained in plant tissues and the vapor removal to the atmosphere. Generally water lose from crops through stomata.

1.1.3 EVAPO-Transpiration:

Evaporation and transpiration occur simultaneously and there is no easy way of distinguishing between the two processes. When the crop is small, water is lost by soil evaporation, but once the crop is well developed and completely covers the soil, transpiration becomes the main process. This combination of two separate processes whereby water is lost on one hand from the soil surface by evaporation and on the other hand from the crop by transpiration is referred as evapo-transpiration (ET). The evapo-transpiration rate is normally expressed in millimeters (mm) per unit time. The rate expresses the amount of water lost from a cropped surface in units of water depth. The time unit can be an hour, day, decade, month or even an entire growing period or year.

1.2. EVAPO-Transpiration Concepts:

Distinctions are made between reference crop evapotranspiration (ETo), crop evapo-transpiration under standard conditions (ETc) and crop evapo-transpiration under nonstandard conditions (ETc). ETo is a climatic parameter expressing the evaporation power of the atmosphere. ETc refers to the evapo-transpiration from excellently managed, large, well-watered fields that achieve full production under the given climatic conditions. Due to suboptimal crop management and environmental constraints that affect crop growth and limit evapo-transpiration, ETc under non-standard conditions generally requires a correction.

1.3 Reference Crop EVAPO-Transpiration (ETc):

The reference crop evapo-transpiration or reference evapotranspiration and is denoted by ETo. The concept of the reference evapo-transpiration was introduced to study the evaporative demand of the atmosphere independently of crop type, crop development and management practices. As water is in large quantities available at the reference evapo-transpiring surface, soil factors do not affect ET. ETo values are measured or calculated at different locations or in different seasons are comparable as they refer to the ET from the same reference surface. The only factors affecting ETo are climatic parameters. Consequently, ETo is a climatic parameter and can be computed from weather data. ETo expresses the evaporating power of the atmosphere at a specific location and time of the year and does not consider the crop characteristics and soil factors. The FAO Penman Monteith method was recommended as the sole method for determining ETo. This method was selected because it closely approximates grass ETo at the location evaluated, is physically based, and explicitly incorporates both physiological and aerodynamic parameters. Moreover, procedures have been developed for estimating missing climatic parameters.

1.4. Crop Evapo-Transpiration under Standard Conditions (ETo):

The crop evapo-transpiration under standard conditions is denoted as ETo, the evapo-transpiration from disease-free, well-fertilized crops, grown in large fields, under best possible soil water conditions, and achieving full production under the given climatic conditions. The amount of water required to compensate the evapo-transpiration loss from the cropped field is defined as crop water requirement. Although the values for crop evapo-transpiration and crop water requirement are identical, crop water requirement refers to the amount of water that needs to be supplied, while crop evapo-transpiration refers to the amount of water that is lost through evapo-transpiration. Crop evapotranspiration can be calculated from climatic data and by integrating directly the crop resistance, albedo and air resistance factors in the Penman-Monteith approach. As there is still a considerable lack of information for different crops, the Penman-Monteith method is used for the estimation of the standard reference crop to determine its evapo-transpiration rate, i.e., ETo. Experimentally determined ratios of ETc/ETo, called crop coefficients (Kc), are used to relate ETc to ETo or ETc = Kc ETo. Crop coefficient (Kc) is defined as the ratio of ET from a crop or soil surface to ET from a fully vegetated surface covering the soil. ETo is determined by the crop coefficient approach whereby the effect of the various weather conditions are incorporated into ETo and the crop characteristics into the Kc coefficient. ETc = Kc ETo Where, ETo = Crop Evapo-transpiration (mm d-1), Kc = Crop coefficient (dimensionless), ETo = Reference crop Evapo-transpiration (mm d-1).

1.5 Crop Evapo-Transpiration under Non-Standard Conditions:

The crop evapo-transpiration under non-standard conditions (ETc) is the evapo-transpiration from crops grown under management and environmental conditions that differ from the standard conditions. The real crop evapo-transpiration may deviate from ETc due to non-optimal conditions such as the presence of pests and diseases, soil salinity, low soil fertility, water shortage or water logging. This may result in scanty plant growth, low plant density and may reduce the evapo-transpiration rate below ETo.

2. OBJECTIVES

The purpose of the present study is to workout reference crop Evapo-transpiration for Jhabua district by using various methods and to compare them. To achieve the goal following steps are proposed:
3. LITERATURE REVIEW:

R Gautam & A. Sinha (2016) focused on evapotranspiration modelling and forecasting, since forecasting would provide better information for optimal water resources management. Nithya KB and Shivapur AV (2016) determined the crop water requirement of few selected crops for the command area in Tarikere taluk in Karnataka state, India. Dabral & Pandey (2016) identified a suitable alternative to the FAO-56 method in the irrigation project for formulae case study. Adamala S, Rajwade Y & Reddy K (2015) studied an estimation based on Normalized Difference Vegetation Index (NDVI) from LANDSAT images.

4. ESTIMATION OF EVAPOTRANSPIRATION:

The ET estimation methods are generally grouped into temperature, radiation and combination theory. Following methods were studied under the present title: - FAO-56Method (Penman-Monteith) - Turc method -Makkink method. Various meteorological parameters and methods are used in calculation of the crop evapotranspiration detailed below:

4.1 FAO-56 Penman-Monteith Method

The FAO-56 Penman-Monteith equation is a modification of the Penman (1963) equation. The main difference is that the Penman-Monteith equation includes the effect of canopy resistance on evapo-transpiration. Allen et al. (1996, 1998) presented the following form of the Penman-Monteith model for estimation of ET₀ in mm/day:

\[
ET₀ = \frac{0.408((Rₑ - 0.1) + \frac{900}{\gamma(Tₑ(Tₑ+273))})U₂}{\Delta+\gamma} = \frac{900}{\gamma(Tₑ(Tₑ+273))}U₂
\]

Where,
- \( Tₑ \) is average air temperature, \(^{°}C\); 
- \( U₂ \) is wind speed measured at 2 m height, [m s\(^{-1}\)]; and 
- \( \gamma \) = Psychometric constant (kPa °C\(^{-1}\)).

4.2 Turc method:

Turc (1961) simplified the earlier version of an equation for potential ET for 10 day periods under general climatic conditions of Western Europe. He proposed the following equations for two humidity conditions:

\[
ET₀ = 0.013 \frac{Tₑ}{Tₑ+15}(Rₑ + 15)^\frac{1}{\lambda}
\]

(For RH\(_{mean}\)>50%)

\[
ET₀ = 0.013 \frac{Tₑ}{Tₑ+15}(Rₑ + 50)^{\frac{1}{\lambda}}(1 + \frac{(50 - RH_{mean})}{70})
\]

(For RH\(_{mean}\)<50%)

Where,
- \( Rₑ \) are solar radiation (MJ m\(^{-2}\) day\(^{-1}\)), 
- \( \lambda \) = the latent heat of vaporization (MJ kg\(^{-1}\)).

4.3 Makkink Method:

This is another simplified equation combination of the original Penman equation; it degrades the aerodynamic component and replaces the net radiation balance with incoming shortwave solar radiation (Rs). The equations:

\[
ET₀ = 0.61 Rₑ \frac{\Delta}{\Delta + \gamma 2.45} - 0.12
\]

Where,
- \( ET₀ \) = Reference Crop Evapo-transpiration (mm/day) 
- \( \Delta \) = Slope of saturation vapor pressure curve at air temperature T (kPa °C\(^{-1}\))
- \( \gamma \) = Psychometric constant (kPa °C\(^{-1}\))
- \( \lambda \) = Latent heat of vaporization, 2.45 (MJ kg\(^{-1}\))
- \( Rₑ \) = the incoming solar radiation (MJ m\(^{-2}\) day\(^{-1}\)).

5. METHODOLOGY AND ANALYSIS:

The methods for calculating evapo-transpiration from meteorological data require various climatologically and Physical parameters. Some of the data are measured directly
in weather stations for the remaining data India water portal and swat websites were referred.

5.1. METHODOLOGY:

Crop evapotranspiration under different methods were calculated using their respective formulas. Parameters were separately calculated using Microsoft excel, then applied to final formula sheet. Data chart obtained after applying the formulas under different methods are shown -

6. RESULTS AND DISCUSSION:

ET₀ values estimated by different methods were used for inter comparison of different methods. The ET₀ values obtained by different methods were compared with the FAO-56 Penman-Monteith method.

SEE values were calculated as follows:

\[
SEE = \left( \frac{\sum (Y_i - \bar{Y})^2}{n-1} \right)^{\frac{1}{2}}
\]

SEE = Standard Error of Estimate; \( Y_i \) = ET₀ estimated by the FAO-56 Penman Monteith method; \( \bar{Y} \) = corresponding ET₀ estimated by the comparison method; and \( n = \) total number of observations. The SEE gives equal weight to the absolute difference between the standard method and the comparison method. It is a measure of the goodness of fit between ET₀ values estimated by the different methods and standard method. The SEE has units of mm/day and (n-1) degrees of freedom.

7. LINEAR REGRESSION ANALYSIS

Linear regression analysis performed between the \( E_{T_0} \) Estimates by the Standard and Comparison Methods using following relationship:

\[
E_{T_0 \text{ method}} = b \cdot E_{T_0 \text{ different Method}}
\]

Where, \( b \) is the regression coefficient. The use of regression through the origin was selected to evaluate the goodness of fit between \( E_{T_0} \) method estimates and the FAO-56 Penman-Monteith estimates because both values should theoretically approach the origin when actual \( E_{T_0} \) is zero. The results are discussed below.

The results of linear regression analysis are given below:

8 CONCLUSIONS

1. The changing global climate has significant on evapo-transpiration and hence there is a need to estimate continually updated evapo-transpiration. In the present study, the \( E_{T_0} \) is calculated by various methods based on Jhabua meteorological and the study is also carried out to compare evapo-transpiration by different methods and to develop interrelationship of FAO-56 penman-Monteith method with other methods which facilitate the calculations using FAO-56 pm in case of non-availability of data for the use of MPM. Table (6.15) shows equations for the relationship of various methods with FAO-56PM.

2. TURC method gives the lowest \( E_{T_0} \) value and in comparison with the Penman-Monteith method.

3. The relationship developed between different methods and Penman-Monteith method can be used to calculate \( E_{T_0} \) for Penman-Monteith method under non-availability of data.
