Abstract - The high temperature synthesis results in coarsening of the particles which ultimately quenches the surface properties of a material. This will lead to poor performance of the Dye sensitized solar cell. Therefore we aim at synthesizing a single phase A-site deficient La doped SrTiO3 (LST) by Pechini method at lower temperatures. It is expected to result in higher porosity and surface area which would aid for better adsorption of the dye molecules onto the material and the Lanthanum doping would contribute for more vacancies which are really important for increasing the conductivity. Thus, the LST powders synthesized by Pechini method would save the energy needed for calcination process and increase the porosity, active surface area, enhancing physical and electrochemical properties of DSSC anode in synergism with La doping.

Key Words: Pechini, adsorption, surface area, porosity, doping, conductivity.

1.INTRODUCTION

The photovoltaic effect was discovered by Alexandre-Edmond Becquerel, who was a French physicist, in 1839. This was the beginning of the solar cell technology. Becquerel’s experiment was done by illuminating two electrodes with different types of light. Dye-Sensitized Solar Cells (DSSCs) have attracted widespread interest since their first description by Grätzel and O'Regan [1] as an influential method for Dye Sensitized Solar Cell Application. In a conventional DSSC, solar energy is converted to electricity through light absorption by dye molecules attached to a mesoporous semiconductor, green leaves absorb the sunlight, in order to convert water and CO₂ to oxygen and carbohydrates. After light absorption by the dye molecule, the resulting excited dye injects an electron into the conduction band (CB) of the semiconductor, and the oxidized dye is in turn regenerated by a redox mediator, normally iodide/triiodide, in a surrounding electrolyte. The cycle is closed by the reduction of the redox couple at a платинов electrode and electrically regenerate the dye molecules. Another TCO covered substrate with a thin Pt layer (few nm) serves as counter electrode, to promote the reduction of the triiodide [7,8]. One of the crucial parts in DSSCs is the dye or photosensitizer. Generally, metal complexes photosensitizers consist of a central metal ion with ancillary ligands having at least one anchoring group. Light absorption in the visible part of the solar spectrum is due to a metal to ligand charge transfer (MLCT). The central metal ion is therefore a crucial part of the overall properties of the complexes. Ancillary ligands, typically bipyridines or terpyridines, can be tuned by different substituents (alkyl, aryl, heterocycle, etc.) to change the photophysical and electrochemical properties and thus improve the photovoltaic performance. In this study, LST(Lanthanum doped Strontium Titanate) powders were synthesized by Pechini method in order to increase surface area and reduce the calcination temperature at which pure perovskite structure can be obtained [9, 10].

2. EXPERIMENTAL PROCEDURE

(La0.3Sr0.7)0.93TiO3 powders were synthesized by Pechini method. Titanium iso propoxide (Ti(OCH(CH₃))₄) was dissolved in ethanol (99.9 %) for stabilization, and then distilled water was added to the solution. After stirring for 1 h, the stoichiometric amount of La(NO₃)₃.6H₂O (Sigma Aldrich, 99 %) and Sr(NO₃)₂ (Sigma Aldrich, 99 %) was dissolved in the solution, and nitric acid (HNO₃) was added as a peptizing agent. The solution was stirred for 3 h, and citric acid (C₆H₇O₆) was added into the solution. Next, ethylene glycol (C₂H₄O₂) was added in the solution, and the solution was strongly stirred at 70° C for 1 h. The transparent solution was gradually changed to the LST gel. With the gel formation, the temperature increased to 180° C to obtain the LST powder. The LST powder was calcined at 600°C temperature for 5 h in air [11].
3. RESULTS & DISCUSSION

Fig -1: XRD patterns of SrTiO₃ SrLaTiO₃ powder calcined at 600°C for 5h

The phase and crystallinity were examined by XRD over 2θ angle from 25° to 75° shown in (fig.1). As the Lanthanum percentage increases, the major peak at 32° corresponding to (110) plane broadens and this is due to the reduction of crystallite size on doping with Lanthanum. Crystallite size is calculated using Scherrer equation, crystallite size of SrLaTiO₃ is 6nm [11].

Fig -2: SEM images of (a) TiO₂; (b) SrTiO₃; (c), (d) SrLaTiO₃

SEM images of (a), (b) and (c) confirms the formation of Spherical morphology of TiO₂, SrTiO₃ and SrLaTiO₃ nanoparticles respectively and SEM image of (d) shows the cross sectional SEM image of SrLaTiO₃ respectively.

Fig -3: (a), (b) UV-Visible Spectroscopy for SrLaTiO₃ at 254nm and Tauc plot for SrLaTiO₃

It shows the Bandgap of SrTiO₃ is 3.2eV. On doping the Lanthanum nitrate hexahydrate to the strontium titanate the bandgap of the material increased to 3.5eV, the wide bandgap which is required for photo anode of dye sensitized solar cell.

Table 2 shows the BET-BJH analysis, it was clear that the Lanthanum doped Strontium titanate has the surface area
(3.0236m²/g), the pore volume (0.002845cm³/g), and the mean pore diameter (11.12mm). It shows the prepared anode material has sufficient surface area for Dye sensitized solar cell application [11].

4. CONCLUSION

The narrow diffraction peaks are observed at 32°, demonstrates the crystalline Lanthanum doped strontium titanate and the SEM image confirms the spherical morphology of SrLaTiO₃. The UV-Vis Spectroscopy of SrLaTiO₃ shows 3.5eV wide bandgap which is necessary for the photo anode material of the DSSC. EDS result shows that the quantitative analysis of the elements present in the sample and confirms the presence of Lanthanum and BET results shows high surface area, pore volume and pore diameter of SrLaTiO₃ which improves the adsorption of dye and hence increases the efficiency due to the increase in light absorption.

ACKNOWLEDGEMENT

I would like to express my sincere thanks and gratitude to Dr. M.Manohakini, Assistant Professor, Centre for Nanoscience and Technology, Anna University, Chennai-25 for giving me an opportunity and guiding me in doing my project. I would also like to thank Dr. M.Ariyanandhan, Associate Professor, Centre for Nanoscience and Technology, Anna University, Chennai-25 and Prof. Dr. P. Ramasamy, SSN College of Engineering for taking great effort in providing I-V characterization. Finally I thank DST Nano Mission 2015-2020 for the financial support and all faculty and research scholars of Centre for Nanoscience and Technology, Anna University, Chennai-25 for their valuable support to carry out this project.
