**Abstract:** In this research work welding simulation was carried out by experimental and also on Solid work software to find out the value of stress and deflection under different loading condition. The numerical simulations show that the concentration of stress is maximum near to the joint and at the corner where the cross section has suddenly changed. In order to find out the most optimum load, the joint can bear is calculated by using experimental method in modern universal testing machine (UTM). It is very important to check & compare the solid work simulation result with the result of physical test or experiment in which the real behavior of specimen can be observed. The research work deals with the physical test of specimen whose main purpose is to find out the optimum material, geometry and strength characteristics of butt weld joint. The specimen of weld joint is tested on UTM machine and corresponding output parameter as stress and deflection is monitored. The result obtained by physical experiment is validated by using different numerical approaches as Solid works simulation.

---

**II. Problem Identification**

The present study deals with finite element analysis of welded butt joint of circular bar of 13 mm diameter under different tensile loading of alloy steel. In this research work, welding strength of material is calculated by using FEA technique. In order to find out the behavior of stress distribution and plot of deflection is verified by applying the experimental method with UTM machine.

---

**Fig. 2 Schematic representation of welded joint**

An edge preparation has done before performing the welding process for proper welding process. Same boundary condition has applied for analysis of weld strength.
III. Methodology

1. Experimental Method:

A specimen were machined and welded to investigate the stress in butt joint. Specimen designed to show the detail that the strength of connected element has to be higher than the strength of the welded joint. The rod is turned into lathe to get the desire shape and size and after that, it cut in hack saw and prepared edge for proper welding process. After the edge preparation, the specimen is welded by using arc-welding process with 6 mm weld size.

A universal testing machine having specimen holding unit to assemble the job in proper orientation, generally for tensile test it’s available in upper end of the machine. The object or specimen are fixed with the specimen holding tools and gradually applying the load to know the nature of deflection of specimen and its stress distribution with respect to the load. A control unit is also available with the modern universal testing machine to plot and print the graph of stress-strain curve of object.

The welded rod consist of 10 mm diameter is tested on UTM machine and start with the load 6 KN and the graph plotted with the increment of 6 KN, corresponding deflection is recorded and plotted on the graph.

2. FEA analysis of welding joints

The new generation of CAD/CAE software's followed the rapid progress in industry, focusing on manufactory. Lately, highly developed and complex features were introduced to empower CAD software, allowing it to satisfy the advanced requirements dictated by the new industry. ANSYS, CATIA, Pro-engineer, Autodesk, and Inventor are the most commonly used software's in this field. ANSYS is a powerful software tool to determine the effect of real time simulation of physical condition. It consist of a wide range of workbench to determine the desire output in the form of graphical representation of chart and curves.

The Finite Element Method (FEM) has formed into a key, imperative innovation in the displaying and reproduction of innovative designing frameworks in different fields like development transportation, interchanges, et cetera. In building such propelled designing frameworks, architects and creators experience an advanced procedure of displaying, reenactment, representation, investigation, outlining, prototyping, testing, and ultimately, manufacture. Note that much work is included before the creation of the last item or framework. This is to guarantee the usefulness of the completed item, and additionally for cost viability. The procedure is delineated as a flowchart in Fig. 4.4. This procedure is frequently iterative in nature, implying that a portion of the methodology are rehashed in view of the
outcomes got at a present stage, in order to accomplish an ideal execution at the most reduced cost for the framework to be constructed. Along these lines, systems identified with displaying and reproduction in a quick and powerful way assume an inexorably essential part, bringing about the utilization of the FEM being duplicated various circumstances along these lines.

A ceaseless capacity of an obscure field variable is approximated utilizing piecewise straight capacities in each sub-space, called a component shaped by hubs. The questions are then the discrete estimations of the field variable at the hubs. Next, legitimate standards are taken after to set up conditions for the components, after which the components are ‘tied’ to each other. This procedure prompts an arrangement of direct arithmetical synchronous conditions for the whole framework that can be unraveled effortlessly to yield the required field variable.

3. Physical Problems in Engineering

There are various physical building issues in a specific framework. As specified before, in spite of the fact that the FEM was at first utilized for pressure examination, numerous other physical issues can be tackled utilizing the FEM. Scientific models of the FEM have been figured for the numerous physical marvels in building frameworks. Regular physical issues unraveled utilizing the standard FEM include: Mechanics for solids and structures.

- Heat transfer.
- Acoustics.
- Fluid mechanics.

The conceptual understanding of the methodology of the FEM is the most important, as the application of the FEM to all other physical problems utilizes similar concepts. Computer modeling using the FEM consists of the major steps discussed in the next section.

4. Computational Modeling Using the FEM

The conduct of a wonder in a framework relies on the geometry or space of the framework, the property of the material or medium, and the limit, starting and stacking conditions. For a designing framework, the geometry or space can be extremely unpredictable. Further, the limit and introductory conditions can likewise be muddled. It is accordingly, as a rule, exceptionally hard to unravel the administering differential condition through diagnostic means. Practically speaking, a large portion of the issues is fathomed utilizing numerical techniques. Among these, the techniques for area discretization championed by the FEM are the most prevalent, because of its common sense and flexibility. The system of computational displaying utilizing the FEM extensively comprises of four stages:

- Modeling of the geometry.
- Meshing (discretization).
- Specification of material property.
- Specification of boundary, initial and loading conditions.

**Modeling of the Geometry**

The modeling of actual model of component is very complex problem in FEA so a proper care and attention is required to create the geometry of component.
Meshing

Meshing is performed to discretize the geometry created into small pieces called elements or cells. Lattice is performed to discretize the geometry made into little pieces called components or cells.

Boundary, Initial and Loading Conditions

Boundary, initial and loading conditions play an important role in solving the simulation. Inputting these conditions is usually done easily using commercial pre-processors, and it is often interfaced with graphics. Users can specify these conditions either to the geometrical identities (points, lines or curves, surfaces, and solids) or to the elements or grids.

Numerical Solution by Solid works Simulation

On applying the relevant boundary conditions in the form of load and constraints, we achieve the stress zones and plot of deflection. In order to clearly differentiate all two-test specimen at same boundary condition, a separate analysis file is used to investigate the nature of stress and deflection of welded rod assembly.

Results & Discussions

Comparison of FEA result with Experimental method

Stress is being calculated for the butt welded joint under tensile loading at various loading condition. The specimen is tested for different loading values from 6KN to 54KN & corresponding induced stress and deflection are calculated.

Conclusion

- The result of study shows that the numerical method can also describe the stress and deflection state with sufficient precision.
- In case of ANSYS Simulation, we can say that this approach is very near to the actual experimental method.
- Based on the experiment there were obtained parameter of real stress distribution that will be used as reference parameter for further study.
- The numerical result may more filtered by using fine meshing of cad geometry but subjected to more ram and graphics requirement which is possible only in works station.
