Abstract - It is useful to detect human activities or events, counting people in crowd, identifying the vehicle number and many more. Analyzing a video for activity detection is tedious as there are many factors which contribute to the performance of the detection system. Major issue is the quality of the video. Today advances in technology has made video recording possible from a tiny smart phone to satellite captures.

The major applications of Human Activity Detection vary from Content-based Video Analytics, Robotics, Human-Computer Interaction, Human fall detection, Ambient Intelligence, Visual Surveillance, and Video Indexing etc. This paper collectively summarizes and deciphers the various methodologies, challenges and issues of Human Activity Detection systems. Variants of Human Activity Detection systems such as Human Object Interactions and Human-Human Interactions are also explored.

Key Words: Support Vector Machine (SVM), Feature Detector, Classification, Feature descriptor

1. INTRODUCTION

Video analytics is the analysis process in large volumes of real time or stored videos. It is useful to detect human activities or events, counting people in crowd, identifying the vehicle number and many more. Analyzing a video for activity detection is tedious as there are many factors which contribute to the performance of the detection system. Major issue is the quality of the video. Today advances in technology has made video recording possible from a tiny smart phone to satellite captures. Taking into consideration the quality of video as a major concern in this paper emphasis is on improving the quality of video and to detected the activity of human. The activity considered is limited to walking, jogging and running. Appropriate feature extraction and selection processes will be inculcated to implement the Support Vector Machine to detected the activity. It is suitable for creating set of hyper planes in an n dimensional space dividing the samples in to the regions with maximum margin. Video formats to be considered in the paper would be .avi, .mp4 and .mpg. The major Steps involved in activity detection are as follows.

Numerous attempts have been made in this field to automatize video surveillance but each and every approaches has its own pros and cons. Table 1 shows the spectrum of such approaches. On the basis of prior knowledge and human involvement in the learning process, the research in human activity detection can be categorized as supervised, unsupervised and semi supervised.

2.1 Supervised Learning

In this type of learning, a number of models of normal or abnormal behavior are built based on the labeled training samples. Video samples which do not fit any model are classified as abnormal. But this approach is limited to only events that are well defined and would require sufficient training data. However, real world video samples would mostly contain events that are not well defined and such events are rare and hence sufficient training samples are not available.
2.2 Unsupervised Learning

In this type of learning, a number of models of normal or abnormal behavior are built based on the labeled training samples. A video sample which does not fit any model is classified as abnormal. But this approach is limited to only events that are well defined and would require sufficient training data. However, real world video samples would mostly contain events that are not well defined and such events are rare and hence sufficient training samples are not available.

3. Methodology

Table 1 shows a brief summary of latest research works in the field of human behavior detection.

| RGB data | activities. They use the Spatio-Temporal Interest Point (STIP) for detection of the important change in the image. |

Weizmann, KTH, MSR action are considered.

Dense trajectories and motion boundary descriptors for action detection

Video representation based on dense trajectories and motion boundary descriptors.

Extract features aligned with the trajectories to characterize are restricted to few parameters

Human Action Segmentation and Detection Using Discriminative Semi-Markov Models

Human action understanding is to jointly segment and detected human actions from an unseen video sequence.

4. Conclusion

In this study we used support vector machines approach for human action detection task. We propose to use a 3D CNN approach in order to extract spatial and temporal features from adjacent video frames with 80x60 resolution. The proposed architecture is trained and evaluated on KTH action detection dataset and achieved a good performance. As a future work, we are planning to use a weighted ensemble learning approach which integrates both of support vector machines and logistic regression in order to classify human actions from 3D CNN based extracted features. Moreover, a genetic algorithm based approach will be used to optimize the weights of the ensemble learner.
