Abstract - While the needs of many individuals with disabilities can be satisfied with power wheelchairs, some members of the disabled community find it difficult or impossible to operate a standard power wheelchair. To accommodate this population, several researchers have used technologies originally developed for mobile robots to create “smart wheelchairs” that reduce the physical, perceptual, and cognitive skills necessary to operate a power wheelchair. We are developing a Smart Wheelchair Component System (SWCS) that can be added to a variety of commercial power wheelchairs with minimal modification. This paper describes the design of a prototype of the SWCS, which has been evaluated on wheelchairs from four different manufacturers.

Key Words: GPS module, obstacle detection, Ultrasonic sensor, joystick control.

1. INTRODUCTION

In the country having differently-abled persons constituting 8.3% of total households having disabled persons, about 99% homes are normal homes, 0.4% are institutional and 0.2% are house-less households. The wheelchair is one of the most commonly used assistive devices for enhancing personal mobility, which is a precondition for enjoying human rights and living in dignity. Wheelchairs assist people with disabilities to become productive members of their communities

Some of the diseases like Alzheimer’s, congestive heart failure, osteoporosis, Glaucoma, cystic fibrosis are mostly affected to the humans who requires wheel chair. Providing appropriate wheelchairs not only enhances mobility but begins a process of opening up a world of education, work and social life. In addition to providing mobility, an appropriate wheelchair benefits the physical health and quality of life of the users by helping in reducing common problems such as pressure sores, progression of deformities and improve respiration and digestion.

2. LITERATURE SURVEY:

Different papers portraying to recognizing the infections and strategies proposing the execution routes as represented what’s more, talked about here.

The EOG traces originate from eyeball and eyelid movements and they are embedded in EEG signals collected from the scalp of the user at three different locations. Features extracted from the EOG traces are used to determine whether the eyes are open or closed, and whether the eyes are gazing to the right, center, or left.

technology (AJAST). used beagle bone black, GSM technology, color conversion, HSV conversion, morphological image processing, Bhattacharyya distance algorithms, relay. The SIAMO project began at the end of 1996 as a continuation of a previous project financed by the ONCE Foundation (National Organization for the Blind of Spain), user-chair interfaces based on oral commands (isolated words with a user-dependent engine), a joystick, and a sensory system composed of ultrasonic and infrared sensors that allowed the detection of obstacles and abrupt unevenness (such as stairs, etc.)

3. HARDWARE

The Real time smart wheelchair is based upon some of the hardware components by developing the process.

3.1 PIC 16F877

The microcontroller that has been used for this project is from PIC series. PIC microcontroller is the first RISC based microcontroller fabricated in CMOS (complimentary metal oxide semiconductor) that uses separate bus for instruction and data allowing simultaneous access of program and data memory.

Fig- PIC16F877(Source: Google Images)

3.2 Joystick

The module gives analog output so it can be used for feeding the analog input based on direction or movement. It can also be connected to a movable camera to control its movement. We can use a Joystick Module with Arduino, Raspberry Pi and any other Micro-controllers.

Fig-3 Joystick Module (Source: Google Images)

3.3 16 x 2 LCD Display

The LCD Display is the electronic device. The LCD display used to see the sicknesses distinguished or ailments name are shown from the LCD.

3.4 Power Supply

The Raspberry pi board need the 5V and 3A power supply to working condition. so, they used to the 5V power supply adapter used to power supply to the raspberry pi board.

3.5 DC MOTOR

12V 55Rpm DC Wiper Motor - ZKE1032 – Left is commonly used as wiper motor for cars, but it can also be used in the field vehicles and projects that require high power. The motor speed is 55rpm and because of the bearing used it has no problem with longer operation times. The motor has 6mm screw holes for mounting and its gear is designed to be on left side of the motor.

3.6 ULTRASONIC SENSOR

It emits an ultrasound at 40 000 Hz which travels through the air and if there is an object or obstacle on its path it will bounce back to the module. Considering the travel time and the speed of the sound you can calculate the distance.

3.7 Global Positioning System

It is the only fully functional GNSS in the world, can be used freely, and is often used by civilians for navigation purposes. It uses a constellation of between 24 and 32 Medium Earth Orbit satellites that transmit precise microwave signals, which allow GPS receivers to determine their current location, the time, and their velocity.
4. Methodology

The ailments distinguishing proof procedure is utilized to MPab software. The MPab Software is the one of the microcontroller processing, programming or library. By using the PIC16B77 microcontroller in the way of controlling the DC motor with the help of DC drive after math Human beings get sophisticated motion.

5. HARDWARE SIMULATION:

When the Joystick controller is turned ON, as like the mechanism of the potentiometer, it activates DC drive towards the DC motor to control the changing direction of Wheel Chair. In between connection of GPS module and LCD display all information and latitude, longitude. If the object is detected the wheelchair takes right and moves 50 cm and turns right and moves forward at a distance of 20 cm and stopped. When we press the switch nearby the joystick it shows the GPS location of the patient.

LCD display shows information are obstacle deducted, Lat, Long, Right, Left, Backward, Forward. When obstacle deducted the wheel chair get turn right and hold some minutes

6. CONCLUSION:

Our wheelchair can be made which can be operated by a Joystick. Output of sensor can be applied to wire transmitter circuit and can received at wheelchair circuit by receiver circuitry. So, GPS module operation can arrange and display the information. Instead of using acceleration motion (eyebrow Movement), in future we can use IOT based human machine interface to move wheelchair in different direction. Using retina movement, we would be able to drive a wheelchair. We can use voice command IC to interface our voice signals with microcontroller.
