**ABSTRACT:** The second order reaction rate constant for the reaction of 5-Chlorosalicylaldehyde with m-toluidine have been reported in ethanol at temperature range 303 to 318 k. The rate of reaction is first order with respect to 5-Chlorosalicylaldehyde and m-toluidine. The rate of reaction increases with increases in temperature. The thermodynamic parameters are used to explain the nature of reaction. Suitable reaction mechanism has been suggested for the formation of the Schiff base. From the effect of temperature on the rate of reaction various thermodynamic parameter have been evaluated.

**Keywords:** Schiff base, 5-Chlorosalicylidene - m-toluidine, kinetics.

## 1. INTRODUCTION:

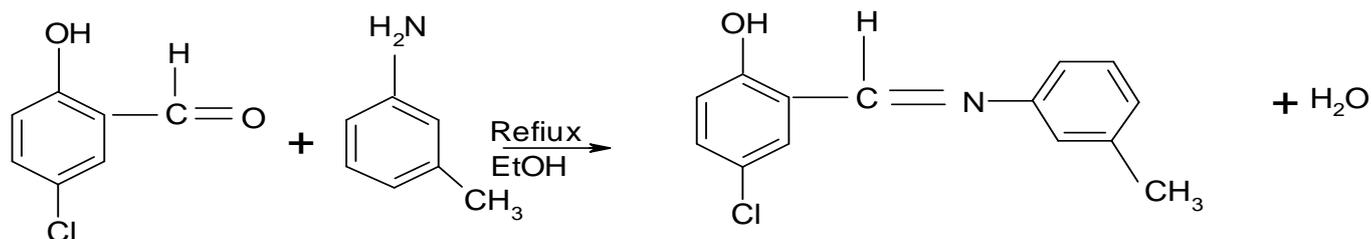

The Schiff bases are also called as imines<sup>1</sup>, anils and azomithines. The kinetic studies of Schiff base formation as well as other carbonyl addition reaction have been interested chemists for some time. Schiff bases derived from m-toluidiens and its derivative with aromatic aldehyde have a wide variety of applications in biological<sup>2,3</sup> and analytical<sup>4</sup> chemistry. Schiff bases are known to be neoplasm inhibitors<sup>5,6</sup> antiviral<sup>7</sup>, anticonvulsants<sup>8</sup>, antimicrobial<sup>9</sup>, anticancer<sup>10</sup>, plant growth regulator<sup>11</sup> and antitubercular<sup>12</sup>, agents. The study of kinetics of formation and hydrolysis of Schiff bases has received a considerable attention due to its relevance to the transformation (conversion) of >C=O to >C=N and vice versa in biochemical processes<sup>13-17</sup>. Schiff bases formation involves a two step reaction between the carbonyl compound and the amino compound. First, addition takes place to form a carbinolamine which then undergoes dehydration<sup>18</sup>. Both step are reversible and subject to general acid – base catalyst<sup>19</sup>.

Literature survey reveals that a great deal of work has been reported on the complexation of metal ions with Schiff bases for the study of structure and stability of the complexes. The catalytic effect of hydrogen, hydroxyl and metal ions on the formation and hydrolysis of imines have been studied by several workers<sup>16, 17, 20-23</sup>. In the present work we reported here kinetic study and mechanism of the formation of Schiff base, 5-Chlorosalicylaldehyde m-toluidine in ethanol medium spectrophotometrically.

## 2. EXPERIMENTAL AND METHODS:

### 2.1 Experimental

Schiff base were prepared by refluxing equimolar quantity of 5-Chlorosalicylaldehyde and m-toluidine in ethanol medium for about three hours. The mixture was cooled and filtered to obtain solid Schiff base and recrystallised from ethanol. The purity was checked by melting point(88°C) and TLC.

**2.2 kinetic measurements: lambert-beer’s law:**

The rate of formation of Schiff base was followed by spectrophotometer at  $\lambda_{max}$ . By using UV-VIS, 1601 Shimadzu Spectrophotometer. The basis of the spectrophotometry is Beer’s law. This relates the absorbancy of a solution to the concentration of the species present. The prerequisite of the spectrophotometry is the validity of the Beer’s law. It is possible to ascertain the concentration of a given species in solution if it absorbs radiation of a particular wavelength and obeys Beer’s law. True variation of this law can arise when moderately concentrated solutions are used. The law is obeyed only in dilute solutions.

**2.3 Standard curves:** The solution of Schiff base of various concentrations (0.001 M to 0.005 M) was prepared using ethanol solvent. Using 0.005 M solution,  $\lambda_{max}$  was determined. The absorbance of each coloured solution was then measured, at this  $\lambda_{max}$  447.5 nm. The readings are recorded in Table-1. The plot of absorbance (optical density) versus concentration of the Schiff bases has been obtained as a straight line (Fig-1). The plot was used as standard curve for the determination of concentration of Schiff bases for the kinetic measurements.

**Table: 1. Optical Density at  $\lambda_{max}$  447.5 nm.**

Conc. Of SB	O.D
0.000	0.000
0.001	0.264
0.002	0.435
0.003	0.648
0.004	0.838
0.005	1.055

**Fig-1 : Standard Curve O.D Vs Concentration**

**2.4 Experimental procedure for kinetic measurements:**

5-Chlorosalicylaldehyde solution (25ml) of desired molarity was taken into 50 ml flask. In another 50 ml flask m-toluidien solution (25 ml) of desired molarity were taken. Both the flasks were then allowed to stand in thermostatic water bath to attain the required temperature. Then content of the flask having m-toluidien solution transferred to the flask containing 5-Chlorosalicylaldehyde. Thus obtained reaction mixture was thoroughly shaken and kept in thermostatic water bath at desired temperature. After mixing, the reaction mixture was transferred to a quartz cell and the increase of absorbance due to Schiff base formation with time was followed against the blank kept in another quartz cell at  $\lambda_{max}$ . At different time intervals solution was employed to determine optical density. From this optical density, concentration (x) of Schiff base present at particular time was determined with the help of the standard curve. It was observed that this method gave reproducible and quantitative result.

## 2.5. Methods of calculations of the rate constant

For the equimolar quantities of reactants, value of second order rate constant were calculated using relation

$$k = \frac{1}{t} \frac{x}{(a-x)}$$

If concentrations of reactants are different, the values of second order rate constants have been calculated by using relation

$$k = \frac{2.303}{(a-b)t} \log \frac{b(a-x)}{a(b-x)}$$

Where,

t = time in second.

a = initial concentration of 5-Chlorosalicylaldehyde.

b = initial concentration of m-toluidien.

x = amount of Schiff base formed in time t.

Graphical k values were obtained from the slope of the linear plot of  $1/(a-x)$  versus time (t) for equal concentration and plot of  $\log [(a-x)/(b-x)]$  versus time (t) for unequal concentrations.

## 2.6 Order of reaction with respect to 5-Chlorosalicylaldehyde

To determine the order of reaction with respect to 5-Chlorosalicylaldehyde, the reaction has been carried out at different concentrations of 5-Chlorosalicylaldehyde by keeping the concentration of m-toluidien constant at a particular temperature.

van't Hoff's differential method<sup>24</sup> was applied to determine the order with respect to 5-Chlorosalicylaldehyde by equation<sup>25-27</sup>.

$$n = \frac{\log \left[ \frac{dc}{dt} \right]_I - \log \left[ \frac{dc}{dt} \right]_{II}}{\log I - \log II}$$

The amount of product formed (x) was plotted against the time in minutes. From the curve, the values of dc/dt have been calculated.

## 2.7. Order of reaction with respect to m-toluidien

The order of reaction with respect to m-toluidien was determined by varying concentration of m-toluidien by keeping the concentration of 5-Chlorosalicylaldehyde constant at a particular temperature. The order with respect to m-toluidien was determined by applying van't Hoff's differential method. The values of dc/dt were evaluated by plotting amount of product formed (x) against time (t) in minutes.

From the effect of temperature on the reaction rate the energy of activation  $E_a$ , enthalpy of activation ( $\Delta H^*$ ), entropy of activation ( $\Delta S^*$ ), free energy ( $\Delta G^*$ ) and frequency factor (A) were calculated.

### 3. RESULT AND DISCUSSION

Kinetics of formation of Schiff bases was carried out at equal concentration. The second order rate constant was calculated by using equation of second order at equal concentration and graphical  $k$  values determined from the straight line plots of  $1/(a-x)$  versus time.

#### 3.1. Reaction order:

The kinetic study is carried out at different concentration of 5-Chlorosalicylaldehyde ( $1 \times 10^{-3}$  to  $5 \times 10^{-3}$  mol  $\text{dm}^{-3}$ ) at constant concentration of m-toluidien ( $5 \times 10^{-3}$  mol  $\text{dm}^{-3}$ ) in ethanol medium at 303 k. The plot of  $dc/dt$  against  $\log [\text{Cl-S.A}]$  is linear and slope of plot was found to be nearly one, indicates the order with respect to 5-Chlorosalicylaldehyde is first order. Similarly the kinetic study is carried out at different concentration of m-toluidien ( $1 \times 10^{-3}$  to  $5 \times 10^{-3}$  mol  $\text{dm}^{-3}$ ) at constant concentration of 5-Chlorosalicylaldehyde ( $5 \times 10^{-3}$  mol  $\text{dm}^{-3}$ ) in ethanol medium at 303 k. The plot of  $dc/dt$  against  $\log [\text{m-toluidien}]$  is linear and slope of plot was found to be nearly one, indicates the order with respect to m-me aniline is first order.

#### 3.2. Effect of temperature on the rate of reaction:

Kinetic measurements were carried out at four different temperatures 303, 308, 313 and 318 k at constant concentration of  $[\text{Cl-S.A}]$  ( $5 \times 10^{-3}$  mol  $\text{dm}^{-3}$ ) and m-toluidien ( $5 \times 10^{-3}$  mol  $\text{dm}^{-3}$ ) in ethanol. The second order rate constant depends on the reaction temperature<sup>28-29</sup>. The thermodynamic parameters like energy of activation ( $E_a$ ), enthalpy of activation ( $\Delta H^*$ ), entropy of activation ( $\Delta S^*$ ), free energy ( $\Delta G^*$ ) and frequency factor ( $A$ ) were calculated (Table 5). From the value of thermodynamic parameter it is observed that  $\Delta H^*$  and  $\Delta S^*$  are the important parameter in controlling the rate of reactions. The negative value of entropy of activation indicates that activated complex is less probable and rate is slower. The negative values of entropy of activation show that the intermediate transition state is rigid. The relatively small values of  $\Delta H^*$  and the negative  $\Delta S^*$  values are consistent with the reactions which generally proceeds through highly organized transition states<sup>30</sup>. If both the reactants are likely charged, the charge density on the surface in the transition state will be more and hence there can be increase in solvation leading again to a negative  $\Delta S^*$ <sup>31</sup>.

Table: 2. Rate constant.

Temp. (k)	$k \times 10^3$ ( $\text{dm}^3 \text{mol}^{-1} \text{s}^{-1}$ )
303	466.86
308	83.399
313	88.472
318	114.824

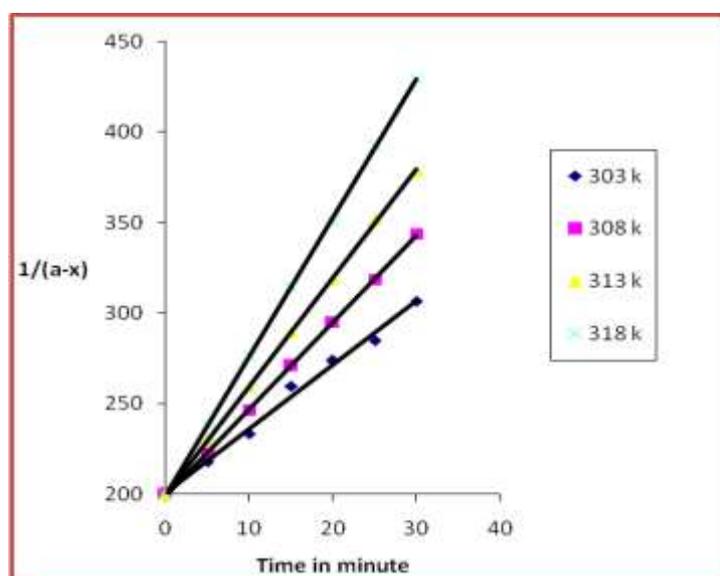

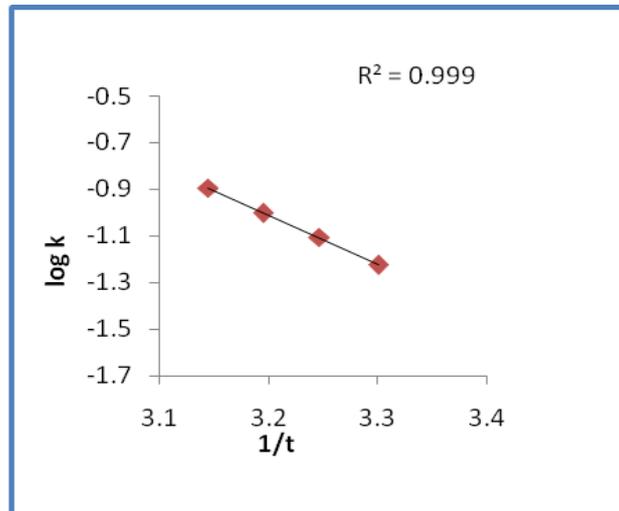

Fig-2: Plot of  $1/(a-x)$  versus  $t$

The rate constant values of Schiff base formation at different temperature are listed in the Table-4. The rate of formation of Schiff bases increases with increasing temperature. The plot of  $\log k$  versus  $1/T$  is straight line (Fig.3)

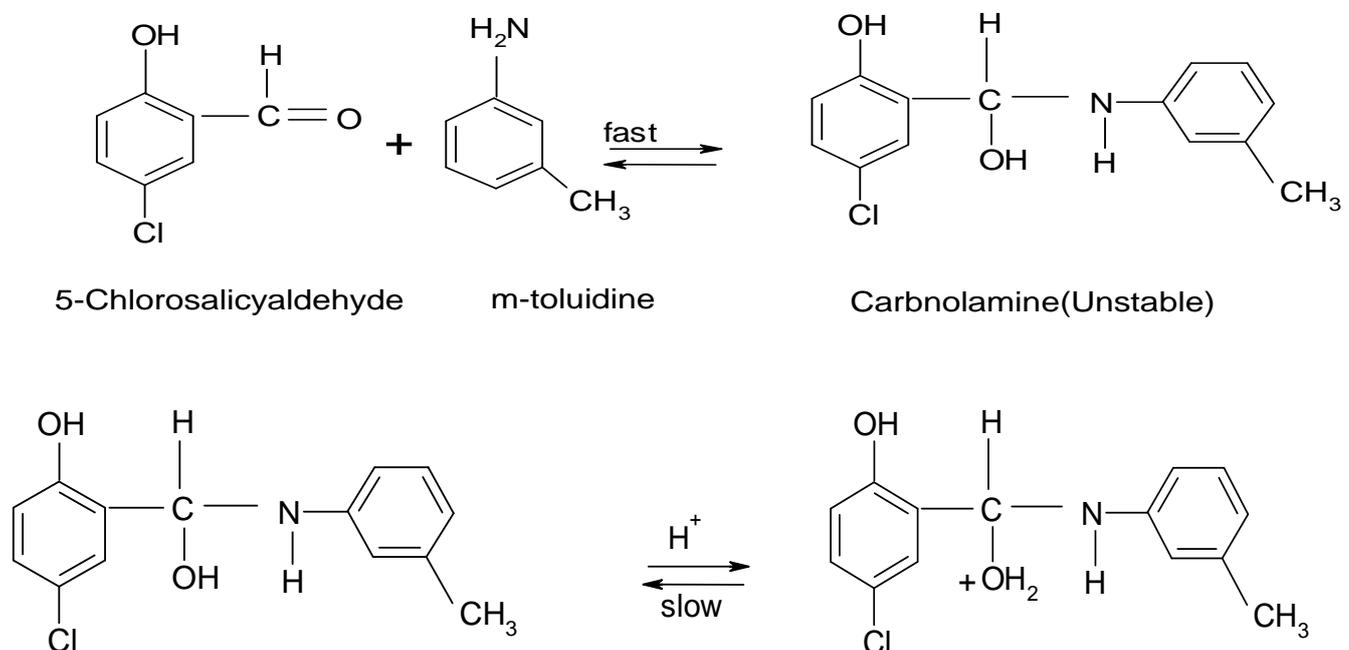

**Table 3. Thermodynamic parameters.**

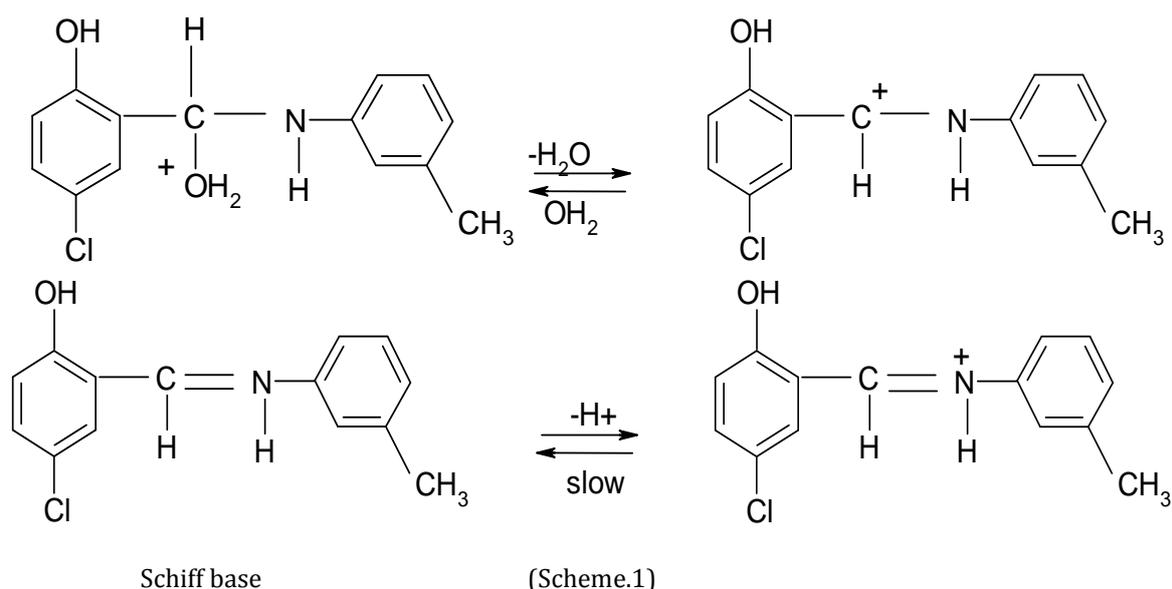

$E_a$	48.355 kJ
$A$	$1.01 \times 10^7$
$\Delta H^*$	45.835 kJ
$\Delta S^*$	$-110.981 \text{ JK}^{-1} \text{ mol}^{-1}$
$\Delta G^*$	$79.463 \text{ kJ mol}^{-1}$

**Fig-3: Plot of  $\log k$  versus  $1/T$**

Schiff bases formation involves a two step reaction between the carbonyl compound and the amino compound. First addition takes place to form a carbinolamine which then undergoes dehydration. Both steps exhibit general acid base catalysis <sup>32,33</sup>.

It was found that the reaction was first order in the carbonyl compounds and first order in amine. Spectroscopic studies have revealed that, under mild acidic condition there is a fast disappearance of the carbonyl function followed by a slow appearance of the product <sup>34</sup>. Under mild acidic condition, rapid addition of amine to the carbonyl compound followed by the acid-catalysed dehydration of the adduct is the rate-controlling step.

An increase in acidity would promote the reaction because it increases the rate of dehydration step. But with a further increase in acidity the nucleophile ( $\text{RNH}_2$ ) may get protonated ( $\text{RNH}_3^+$ ) and, thus deprived of its lone pair of electrons and is no longer in a position to attack the positive carbonyl carbon (Scheme.1).
