ABSTRACT:- Herewith discuss the *T.luteus* and *T. lanuginosus* were showed clear zones when flooded with iodine solution, suggesting their potential to secrete amylase, while remaining fungi were failed to produce amylase. α -amylase production by all the three strains of *T. lanuginosus*, while medium E was poor substratum for α -amylase production. Medium F was more suitable for β -amylase production by *GSLMBKU* strains.Conditions are optimized by maintaing PH. *GSLMBKU-10* could achieve good mycelial growth during its growth on L-asparagine and yeast extract, while it was least in medium containing L-glutamic acid. Glycine was more suitable nitrogen source for the vegetative growth of *GSLMBKU-12*, whereas ammonium sulphate was least preferred. Further confirmed by ANOVA studies.

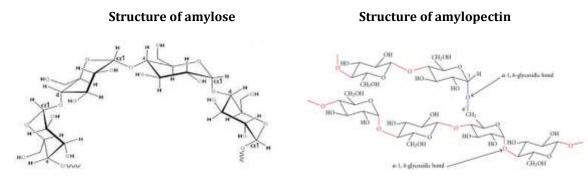

KEYWORDS

Amylases, amylopectin, ANOVA, fungal strain.

INTRODUCTION

Amylases are important hydrolytic enzymes which catalyzes the hydrolysis of polysaccharides such as starch into simple sugars¹. The major industrial sources of starch are the grains of cereals (maize, wheat, rice) and tubers (potato and cassava). Starch is a polymer of glucose linked to one another through the glycosidic bonds²⁻⁴. Starch is composed of two distinct polysaccharides amylose and amylopectin. Amylose is essentially a linear polymer consisting of up to 6000 glucose units with $\alpha(1-4)$ glycosidic bonds. The average amylose content in most common starches ⁵⁻⁶ such as barley, corn and potato, is 20-30%. Amylopectin is a highly branched polymer consisting of short α , 1-4 linked linear chains of 10–60 glucose units and α ,1-6 linked side chains with 15–45 glucose units. Altogether the complete amylopectin molecule contains about 2 000,000 glucose units, thereby being one of the largest molecules in nature. Internal part of amylopectin is considered to be critical to the physical behavior of granular starch.

Amylases are group of enzymes which are capable of digesting these glycosidic linkages found in starches. These enzymes are used in starch processing industries to produce ethanol, glucose and fructose syrups and they are also used in textile, brewing and paper industries⁷⁻⁸. Amylases are widely distributed in plants, animals and microorganisms which differ widely in their properties and mode of action depending on the source. In spite of the wide distribution, the microbial amylases are preferred over plant and animal source for industrial production. This is because of several advantages such as cost effectiveness, consistency, less time and space required for bulk production as well as ease of process modification and optimization. Amylases produced by thermophilic fungi are especially more important because of thermo stable enzymes, which can be used in saccharification processes that occur at high temperature ⁹⁻¹⁰.

MATERIALS AND METHOD

Amylase production by three strains of *T. lanuginosus* on different synthetic media was studied. Simultaneously vegetative growth and pH changes were also recorded and the results are summarized in **Table 1, 2**.Name of the fungus and ANOVA studies mentioned from **Table 3-13**.

α-amylase production by all the three strains of *T. lanuginosus*, while medium E was poor substratum for α-amylase production. Medium F was more suitable for β-amylase production by *GSLMBKU-10*. Whereas, in *GSLMBKU-12* and *GSLMBKU-14* medium B was responsible for maximum β-amylase production. Addition of starch to media was not greatly influenced enzyme production by *GSLMBKU-10*, where as in other two strains, enzyme production influenced by addition of substrate. Nine days incubation was optimum for the enzyme production. Medium D followed by medium C were best substrates for the growth of *GSLMBKU-10*, while *GSLMBKU-12* opted medium B followed by C and *GSLMBKU-14* opted medium B followed by D. Nine days incubation period was optimum for the vegetative growth in all the media tried. Minimum pH changes were recorded and the final pH remained near neutral. The pH range of 5.0 to 8.0. Maximum α-amylase production observed at pH 6.5, whereas pH 6.0 was optimum for β amylase production.. *GSLMBKU-12* could grow in the pH range of 5.0 to 7.5. It failed to grow at pH 8.0. pH 6.0 followed by pH 6.5 followed by pH 7.0 was optimum for α-amylase production and pH 6.0 for β amylase production of angle pH 6.0 to 7.0 was optimum for all the three strains under investigation.**(Text Fig 12,13)**

RESULTS AND DISCUSSION

CONCLUSION

GSLMBKU-10 could achieve good mycelial growth during its growth on L-asparagine and yeast extract, while it was least in medium containing L-glutamic acid. Glycine was more suitable nitrogen source for the vegetative growth of GSLMBKU-12, whereas ammonium sulphate was least preferred. Yeast extract and tryptophan were preferred nitrogen sources for maximum vegetative growth of GSLMBKU-14 and L-aspartic acid and urea was least preferred. Rest of nitrogen sources supported intermediate amount of mycelial growth. Twelve days incubation period was optimum for the vegetative growth of all the three strains under investigation.
