Abstract— Smart system allow users to control various electronic appliances like fan, lights etc. The voice controlled smart system using raspberry pi3b which acts as a smart device with the help of Google Assistance controls multiple devices such as lights and fans connected to it.

Keywords—non smart devices, smart system, raspberry pi

1. INTRODUCTION

The IOT is enabled by the latest developments in RFID, smart sensors, communication technologies and Internet protocols. The basic premise is to have smart sensors collaborate directly without human involvement to deliver a new class of applications. The current revolution in Internet, mobile and machine-to-machine (M2M) technologies can be seen as the first phase of the IOT. In the coming years, the IOT is expected to bridge diverse technologies to enable new applications by connecting physical objects together in support of intelligent decision making.

The Internet of Things is a paradigm where everyday objects can be equipped with identifying, sensing, networking and processing capabilities that will allow them to communicate with one another and with other devices and services over the Internet to accomplish some objective. Internet, the networks of networks avail us the world at one click. This paper is a survey on Internet of Things which is believed to be the next evolution of Internet. The Internet of Things (IOT) bridges the cyber and the physical worlds. Ultimately, IOT devices will be ubiquitous, context-aware and will enable ambient intelligence.

The IoT communication technologies connect heterogeneous objects together to deliver specific smart services. Typically, the IoT nodes should operate using low power in the presence of lossy and noisy communication links. Examples of communication protocols used for the IoT are Wi-Fi, Bluetooth, IEEE 802.15.4, Zigbee, and LTE-Advanced. Some specific communication technologies are also in use like RFID, Near Field Communication (NFC) and ultra-wide bandwidth (UWB).

Another communication technology is Wi-Fi that uses radio waves to exchange data amongst things within 100 m range. Wi-Fi allows smart devices to communicate and exchange information without using a router in some ad hoc configurations. Bluetooth presents a communication technology that is used to exchange data between devices over short distances using short-wavelength radio to minimize power consumption.

Processing units (e.g., microcontrollers, microprocessors, SOCs, FPGAs) and software applications represent the —brain— and the computational ability of the IoT. Various hardware platforms were developed to run IoT applications such as Arduino, ODROID, Friendly ARM, Intel Galileo, Raspberry Pi, Gadgeteer, Beagle Bone, Cubieboard, Z1, Wi Sense, Mule, and T-Mote Sky. There are several Real-Time Operating Systems (RTOS) that are good candidates for the development of RTOS-based IoT applications. For instance, the Contiki RTOS has been used widely in IoT scenarios. Contiki has a simulator called Cooja which allows researchers and developers to simulate and emulate IoT and wireless sensor network (WSN) applications.

Overall, IoT services can be categorized under four classes namely Identity-related Services, Information Aggregation Services, Collaborative-Aware Services and Ubiquitous Services. Identity-related services are the most basic and important services that are used in other types of services. Every application that needs to bring real world objects to the virtual world has to identify those objects.

Information Aggregation Services collect and summarize raw sensory measurements that need to be processed and reported to the IoT application. Collaborative-Aware Services act on top of Information Aggregation Services and use the obtained data to make decision and react accordingly. Ubiquitous Services, however, aim to provide Collaborative-Aware Services anytime they are needed to anyone who needs them anywhere.

2. LITERATURE SURVEY

In today’s world, automation plays a very important role and in this project, an automated way of controlling home appliances through human interaction as well as through self-control of the system itself is provided. The manual mode helps users to control home appliances automatically using PC or any Wi-Fi enabled mobile phone in the same local area network. In automated mode, the system controls the appliances itself depending on some sensor reading, thus making it fully automated. Another feature of the automated mode is the security mode. Through this mode user will be alerted if any intruder enter the main door when the system is active. [1]

It is a low cost and flexible home control and environmental monitoring system. It employs an embedded micro web server in Arduino Mega 2560 microcontroller, with IP connectivity for accessing and controlling devices and appliances remotely. These devices can be controlled through a web application or via Bluetooth Android based Smart phone app. The proposed system does not require a dedicated server PC with respect to similar systems and offers a novel communication protocol to monitor and control the home environment with more than just the switching functionality. To demonstrate the feasibility and effectiveness of this system, devices such as light
switches, power plug, temperature sensor, gas sensor and motion sensors have been integrated with the proposed home control system. [2]

The design of the low cost voice recognition based home automation system for the physically challenged people suffering from quadriplegia or paraplegia (who cannot move their limbs but can speak and listen) to control the various home appliances and can actuate the bed elevation just by the voice commands according to their need and comfort. The proposed system consists of a voice recognition module, Arduino uno microcontroller, relay circuit to and an adjustable bed. The voice recognition module needs to be trained first before it can be used to recognize commands. Upon successful recognition of voice command the Arduino drives the corresponding load with the help of the relay circuit. The adjustable bed elevation can be set to the three different modes as per the user comfort and need. The accuracy of voice recognition module is also measured in different conditions. The experimental results validate the functions of the proposed system. The results show the system can provide great assistance to the physically challenged people without any third person’s assistance. [3]

One of the most promising technologies to enhance the quality of life of quadriplegia patients is smart home environments. Security has a paramount importance for all health information systems, but it is generally overlooked until a major security breach occurs. Especially in an application specifically targeting people with disabilities, ignoring security might have dire consequences therefore they think that proactive measures should be taken by system designers. In this paper, they present SHA, a secure voice activated smart home for quadriplegia patients. The principal contribution of our system lies behind the security mechanisms incorporated in the proposed smart home architecture which has an integrated framework including ambient assistance and remote health monitoring. [4]

The FPGA of an ASR system is implemented in a car environment. The voice feature vectors are extracted by using Mel-Frequency Cepstral Coefficients and compared by using FastDTW algorithms. The recognition rate of the proposed system is 81.5%. Both MFCC and FastDTW algorithms are implemented by Verilog HDL. The target device is chosen as Altera DE2-115. [5]

Smart homes are in huge demand and have gained significant consumer awareness. Smart homes and home automation systems are generally used with reference to a wide range of solutions that includes controlling, monitoring and automating various functions inside a home. In this paper, design of home automation systems using various technologies is proposed and their performances are evaluated. The proposed work is an outcome of a funded project and the systems proposed, designed and reported in this paper can be easily adapted for various applications such as control of machines in machining industries, automotive industry, navigating mobile wireless nodes and automating offices. [6]

The home automation improves the lifestyle of the control of home devices. Technology advancements have made the implementation of embedded systems within home appliances. The abilities and benefits are increased by the home automation. The value of our lives can be improved by automating various instruments or electrical appliances. There is always a stipulation for home automation through mobile phones. Our main objectives are to help old aged people and handicapped to control the home appliances from remote places. Our major focus is on controlling the home appliances from both indoor and outdoor. The mobile application is created and interfaced with the device to control home appliances through Bluetooth and GSM for indoor and outdoor controlling respectively. [7]

Remote home management is one of the developing areas in current technology. This paper describes how to manage and control home appliances using mobile phone, people can use this system to do things in their home from a far place before they reach home. For instance, user may start his/her room cooler or heater so that before they reach home the condition in the room will be conducive, also appliances like washing machine and cooker can be started and if the time taken for this appliances to perform a task is known that can also be set, so that if the time elapses the appliance will automatically switch off itself. To control an appliance the user sends a command in form of SMS from his/her mobile phone to a computer which is connected to the appliance, once the message is received the computer will send the command to a microcontroller for controlling the appliance appropriately. [8]

The main objective of this paper is to develop a home automation system using an Arduino board with Bluetooth being remotely controlled by any Android OS smart phone. As technology is advancing so houses are also getting smarter. Modern houses are gradually shifting from conventional switches to centralized control system, involving remote controlled switches. Presently, conventional wall switches located in different parts of the house makes it difficult for the user to go near them to operate. Even more it becomes more difficult for the elderly or physically handicapped people to do so. Remote controlled home automation system provides a most modern solution with smart phones. In order to achieve this, a Bluetooth module is interfaced to the Arduino board (ATMEGA 328) at the receiver end while on the transmitter end, a GUI application on the cell phone sends ON/OFF commands to the receiver where loads are connected. [9]

The research work investigates the potential of ‘Full Home Control’, which is the aim of the Home Automation Systems in near future. The analysis and implementation of the home automation technology using Global System for Mobile Communication (GSM) modem to control home appliances such as light, conditional system, and security system via Short Message Service (SMS) text messages is presented in this paper. The proposed research work is focused on functionality of the SMS text messages or ON/OFF commands to the receiver where loads are connected. [10]

The concept of serial communication and AT-commands has been applied towards development of the smart GSM-based home automation system. Homeowners will be able to receive feedback status of any home appliances under control whether switched on or off remotely from their mobile phones. PIC16F887 microcontroller with the integration of GSM provides the smart automated house system with the desired baud rate of 9600 bps. The proposed prototype of GSM-based home automation system was implemented and tested with maximum of four loads and shows the accuracy of ≥98%. [11]
Automation is a trending topic in the 21st century making it play an important role in our daily lives. The main attraction of any automated system is reducing human labor, effort, time and errors due to human negligence. With the development of modern technology, smart phones have become a necessity for every person on this planet. Applications are being developed on Android systems that are useful to us in various ways. Another upcoming technology is natural language processing which enables us to command and control things with our voice. Combining all of these, our paper presents a micro controller based voice controlled home automation system using smartphones. Such a system will enable users to have control over every appliance in his/her home with their voice. All that the user needs is an Android smartphone, which is present in almost everybody's hand nowadays, and a control circuit. The control circuit consists of an Arduino Uno microcontroller, which processes the user commands and controls the switching of devices. The connection between the microcontroller and the smartphone is established via Bluetooth, a widespread wireless technology used for sharing data. [12]

Nowadays, the remote Home Automation turns out to be more and more significant and appealing. It improves the value of our lives by automating various electrical appliances or instruments. This paper describes GSM (Global System Messaging) based secured device control system using App Inventor for Android mobile phones. App Inventor is a latest visual programming platform for developing mobile applications for Android-based smart phones. The Android Mobile Phone Platform becomes more and more popular among software developers, because of its powerful capabilities and open architecture. It is a fantastic platform for the real world interface control, as it offers an ample of resources and already incorporates a lot of sensors. No need to write programming codes to develop apps in the App Inventor, instead it provides visual design interface as the way the apps looks and use blocks of interlocking components to control the app’s behavior. The App Inventor aims to make programming enjoyable and accessible to novices. [13]

Each and every part of our life is somehow linked with the embedded products. Embedded systems are the product of hardware and software co-design. Embedded system is becoming an integral part of Engineering design process for efficient analysis and effective operation. From data analysis to hardware work, everywhere embedded products are the main interest because of its reliability and time bound perfection. There is not much time with anyone now a day to give enough in all aspects, so demand of embedded products which serve as we want is high on demand. The present paper describes the design of an embedded system for the control of Temperature &Light intensity with continuous monitoring in a single system using sensors, microcontroller and LCD. It describes the controlling action incorporated in the hardware to control any device connected when specific conditions are met. Further set up is made such that data can be stored for future offline analysis.[15] 

3. BENEFITS OF INTERNET OF THINGS

The potentialities offered by the IoT make it possible to develop numerous applications based on it, of which only a few applications are currently deployed. In future, there will be intelligent applications for smarter homes and offices, smarter transportation systems, smarter hospitals, smarter enterprises and factories. In the following subsections, some of the important example applications of IoT are briefly discussed.

The new Smart Parking sensor’s to be buried in parking spaces to detect the arrival and departure of vehicles. The Smart parking provides extensive parking management solutions which helps motorists save time and fuel (LIBERLIUM, 2013). A significant contribution to congestion arises from motorists searching for accessible parking spaces. Providing accurate information about parking spaces helps traffic flow better, and this will also allow the deployment of application to book parking spaces directly from the vehicle. This will help to reduce CO2 emissions and to minimize traffic jams.

Implementing the Internet of Things in Retail chain monitoring has many advantages: RFID and NFC can be used to monitor almost every link of supply chain, ranging from commodity details, raw material purchasing, production, transportation, and storage, sale of product and after sales services. With the help of IoT, we will track the inventory in the warehouse so that stock can be refilled at the appropriate time for continuous sale and this will reduce the waiting time of customer which result in customer satisfaction, which further results in increased sales.

4. DISADVANTAGES OF INTERNET OF THINGS

Privacy: Internet of Things (IOT) is going to add a lot to our lives, it’s probably going to take our privacy in payment, whether you want it to or not. Concept of being offline, of being unavailable, or simply being alone, will recede. We are standing on the brink of a post-privacy society. After the implementation of IoT, We may be living well in the last era of privacy.

Complexity: Any failure or bugs in the software or hardware will have serious consequences. Power failure can cause a lot of inconvenience. Development needs to be easy for all developers, not just to experts.

Change in Human Behavior: As a society we’re addicted to tech in a way that no generation ever has been before. When we live in a world in which there are countless sensors and smart objects around us, all the time; when the clothes we wear, even things inside our bodies, are smart and connected then change in behavior is obvious. Human will be like robot but with blood.

Environmental Impact: A concern regarding IOT technologies pertains to the environmental impacts of the manufacturer, use, and eventual disposal of all these semiconductor-rich devices. Electronic components are often simply incinerated or dumped in regular landfills, thereby polluting soil, groundwater, surface water, and air. Air will be cover with large dense network.

5. EXISTING SYSTEM

The web based home automation system in which user can interact with the system through a web-based user interface over the Internet. Home appliances like lights, door locks, air conditioners and gates are remotely controlled through a user-friendly web page. Functions of web based system.
Lights and doors are displayed through a web page that can be controlled through web browser and system monitoring of the house in real-time. If a threat is detected, with the help of appropriate wired and wireless motion sensors alarm system will be starts. Alarm system will alert the user and security personnel through Short Message Service (SMS) messages which is highly extensible and customizable.

The system connected to home appliances. This system is developed as a custom-designed processor in Field Programmable Gate Array (FPGA). The system is implemented on a Nios development board cyclone II edition components and interfaces. The main processor interacts with external components, viz. sensors, appliances and devices by using C programming language. User interface is developed by using socket programming, hypertext mark-up language (HTML), JavaScript and Personal Home Page (PHP). The user is able to communicate directly with the board through a web browser.

Home automation is working on cloud principle. With the help of different sensors, monitoring is done. A computer is kept permanently active at home. That computer is there to control the operations with home appliances. Home PC is kept to continuous monitor sensor output. If there is any problem found with the output given by sensors, Home pc is going to report that problem to Cloud Server.

Home PC is responsible for conveying messages towards cloud server. Cloud server will store the information into the database and will take actions according to output. Working of cloud server is to mine the data from database, and convey the relevant message to the HAS owner by a initiating a call/ SMS, and the intelligence part in this system is to call and send SMS to the Technician and report the detailed problem occurred in the appliances.

This system as stated it is energy efficient but it takes lots of energy in sensing the environment as well as to kept a Home PC continuously ON, energy supply to PC is required. As this system required cloud server, one Home PC the system is also more costly than other HAS. This system can be more useful for that who are more living outside and who need to access the appliances from remote location. Functions of cloud based system.

System is using number of sensors to monitor different parameters like light, temperature, humidity to get information about current surrounding area. One computer at home is kept continuously ON to observe the output given by sensors. This computer will give the information to Cloud server side. For storing the phone numbers and relative contact details of the User and the technical persons, their work address, work time, and services they offered there is one module for Registration which helps to store data at server side.

In operational state Cloud server is going to mine the Data gathered from no of sensors, and going to perform the actions like Sending mail/SMS/call to HAS User. This system basically works via a cloud server which is responsible for taking actions on the basis of results provided by sensors situated in home. This system doesn’t require any remote like machine for e.g. Mobile Phone or remote controller to give actions to system, instead of that it acts automatically according to the conditions specified in it which is more useful to have a device free walk and have actions performed by the controller by taking decision by their own.

In SMS based Smart home concept has the main control which implements GSM to provide remote access from PC/laptop. The design consists existing electrical switches and with low voltage activating method provides more safety control in the switches. The switches status is synchronized in all the control system whereby the real time existing switches status is indicated by every user interface. The purpose of system is to control electrical appliances. This design of the system contains the mechanical switches with the modified low voltage activating method, in order to provide safer control to the user. The connection in this system is established by GSM module. This GSM module directly receives /transmits commands from/to PC/Laptop.

The System is placed and deployed on the wall or any empty area in user’s surrounding. The system is capable with communicating with the user’s computer/laptop/smart phone using the Bluetooth wireless connection. Deployed system comes with GUI which is installed on the one of this device.
6. DISADVANTAGES OF EXISTING SYSTEM

- Existing system works only with specific proprietary applications
- No voice control
- No Unified Access to electrical devices
- Works only on smart devices
- Need same Communication Network to ensure proper communication
- Doesn’t work with unified access devices viz., Google Assistant, Amazon Echo DOT, etc.

CONCLUSION

In today’s smart world everyone needs smart devices to enjoy the benefits it provides. But the problem is what to do with the existing non smart devices which don’t provide any of the features of smart devices. The need for smart system will enable to use the non-smart devices as smart device by controlling them over voice commands.
