Abstract: In Road Roughness is a major problem in Indian cities and for rural area it is very big issues. Roughness of road is occur due to heavy traffic, high intensity of vehicles in rural area poor quality of road construction.

Keywords: Roughness.

Introduction

Roughness is not just small undulation of road and pits on road surface.

Roughness measurement can be recorded by various techniques. Such as Drum troop, trailer method, coast-down method, etc. But this method are so complicated and varies assumptions hence the World Bank in 1982 made the International Road Roughness Index method.

In IRI method various values of road index to measure the roughness. But in this method highly interactive sensor vehicles are occur hence it is very costly method. That's why we have developed the new method for measurement of undulation of road surface.

Literature Review

Molenaar and Sweere (1980) Found the impact of road roughness on riding comfort and pavement deterioration. Distinction is made between an inventory and a diagnostic survey. The equipment used for both surveys is described. They are a ride meter for the inventory survey and a high-speed profilometer for the diagnostic survey. Since the ride index, which is given by the ride meter, is dependent on the measuring vehicle, relations are established between the ride index and fundamental indicators of road roughness as determined with the high-speed profilometer. Based on measurements with the high-speed profilometer, the impact of road roughness on the structural deterioration of the pavement and on the riding comfort is calculated. Also, the impact of road roughness on the safety of the road user is described.

Chattiet al. (2017) Roughness of up to 3m/km had no impact on maintenance cost, but the cost would increase beyond that limit, according to the calibrated HDM-4 model. The increase would vary with the exact roughness. IRI decrease by 1m/km resulted in savings up to 24 to 73 billion dollars per year in repair and maintenance cost alone, as 3m/km to 4m/km change would result in 10% increase of operating cost. The variation is not linear either. In this study, various values of roughness need to be calculated. Applied HDM-4 model for U.S. conditions, and they found that for every 1m/km increase of IRI, there is an increase of 1% in tire wear, at 80km/h. The results were obtained for heavy trucks and passenger cars.

Surns (1980) Found that the roughness plays a significant role in roadway accidents and should be considered when evaluating pavement safety as well as when planning and designing safety improvements.

SulaymonEshkabilov (2018) Presented experimental studies from the road profile measurements by employing accelerometers and international roughness index - IRI assessment tools and practical guidelines with respect to measured acceleration data processing in terms of digital filter design and conversion of vertical acceleration data into displacement data. In addition, it shows comparative analysis of measurements with accelerometers and Rod & Level (Leica TS 06 Plus), and gives some recommendations how to process measured data.

Nair and Hudson (1985) developed the predictive pavement serviceability equations based on the serviceability– performance concept. One of the primary objectives of highway agencies in Canada is providing a safe and reliable road network with a good level of service. In the Province of Alberta specific International Roughness Index (IRI) threshold values classify pavements into good, fair, and poor condition categories to manage and schedule rehabilitation and maintenance programs. This research investigated the significant factors that affect the perception of road roughness and established IRI threshold values for good, fair, and poor road condition based on public perception. A questionnaire was designed to investigate the road users' perception and included questions covering gender, age, familiarity with the road, type and model of car, and perception of road roughness. In addition, psychometric scaling analysis was used to develop a set of IRI threshold values for classifying road condition based on public perception in the Province of Alberta. According to the results of the survey, Alberta Transportation threshold values of IRI do not agree with the road users’ opinion and an alternate set
of threshold values was developed.

Chattiet al. (2017) Roughness of up to 3m/km had no impact on maintenance cost, but the cost would increase beyond that limit, according to the calibrated HDM-4 model. The increase would vary with the exact roughness. IRI decrease by 1m/km resulted in savings up to 24 to 73 billion dollars per year in repair and maintenance cost alone, as 3m/km to 4m/km change would result in 10% increase of operating cost. The variation is not linear either. In this study, various values of roughness need to be calculated. Applied HDM-4 model for U.S. conditions, and they found that for every 1m/km increase of IRI, there is an increase of 1% in tire wear, at 88km/h. The results were obtained for heavy trucks and passenger cars.

Karan et al. (1978) Developed relationship between average speed and pavement conditions for two-lane highways. Pavement surface conditions have an influence on traffic safety, operating speed, maneuverability, and driver comfort and service volume. Although many researchers have studied the influence of different roadway characteristics on traffic stream characteristics and performance, little research has been conducted to investigate the impact of pavement conditions on traffic stream characteristics. This research therefore investigates the impact of pavement conditions on traffic speed, the most important traffic stream characteristic. Field data were collected across 13 sites from two-lane, two-way roads in Menoufia and Gharbia governorates, Egypt. Each site included two sections, distressed and undistressed. Road geometry and pavement condition characteristics were collected manually while traffic surveys were carried out using automatic traffic recorders. The data analysis revealed that poor pavement conditions caused a large variation in vehicle speeds and consequently made the speed distribution deviate from the normal distribution. There was a significant difference between the mean speeds for different classes of vehicles.

Research Gap

The There is need to evolve a strategy towards the reduction of urban road roughness as it's reducing overall road performance as well vehicles too. In previous studies of the impact of pavement roughness on life cycle greenhouse gas emissions, it was assumed that pavement roughness has no impact on vehicle speed, which implies that travel behaviour does not change before and after the performance of pavement preservation and rehabilitation processes that reduce pavement roughness for some particular vehicles only. Estimate free-flow speed, this study attempts to verify this assumption using IRI as an indicator of pavement roughness on free-flow speed. Only few studies have provided permanent solution to find road roughness. It is costlier to find road roughness using different machines as well GPS. So this study implies suitable method to find road roughness as well its effect on all kind of vehicles.

From the literature survey it is observed that the road roughness can be reduces by varies different methods and can be calculate using different methods. Only few studies have provided permanent solution to reduce the traffic congestion. Therefore, present study is important and its finding will be useful in road roughness measurement and preventive measures. From the total literature review, no one author have stated economical solution to find road roughness and about its reduction. Therefore, there is scope for proper strategy planning to detect and reduce road roughness.

Methodology

As per above mention we are created the new method by using leveling staff and auto level we have measured the road roughness in context of centerline.

The method we adopted is basically called the centerline method. (C.L.A)

Figure 1.1: Road Profile

By using planimeter calculate the area of curve and the use the following formula to calculate the roughness of road.

$$\frac{A_1 + A_2 + A_3 + \ldots}{L} = \frac{\Sigma A}{L}$$

Figure 1.2: Statistical Formulation

Study Area

To calculate the road roughness it is necessary to fulfill all the criteria of roughness like heavy traffic, high intensity, etc.

We have selected the service road of NH-3 in Nashik and selected the two landmark "Meenatai Thakare Stadium" to "Amruthdam" having distance about 1000 M.

In this patch of road we have surveyed very bad condition of road pavement which was most likely suitable for our area of practice.

We have also used the "Road Bounce Application" for
the measuring the actual road condition for selection of road / area of practice.

With the base of above graph we have studied and calculated that as the roughness increases the vehicle speed decreases.

Now-a- days high speed transportation is so important to reduce the transportation time of good and passenger. Hence high road roughness is affecting the transportation facility.

2) Impact on Fuel economy:

The main expectation of vehicle owner is that the vehicle acquire the low fuel. The fuel economy is not 100 % based on road roughness but some percentage of roughness is considered.

From above graph shows that roughness affects the fuel economy, because vehicle engine is acquires extra fuel in undulated road condition. In small or large pits, low roughness increases the fuel economy.

3) Impact on comfort:

Passenger comfort is totally based on road condition in rural area its comfort is important issues on travelling. The driver’s response to the high levels of road roughness is to reduce the vehicle speed to keep the vehicle ride within the tolerable limits for comfort, safety and protection of vehicle. The free flow vehicle speed are thus constrained by the ride response, among other factors.
From the above graph show that the roughness increases the comfort level of passenger is reduced.

4) Impact on Vehicle damage factor:

As importance of the road roughness being an important aspect as discussed above, involving the response of vehicle itself to the forces coming in through the wheels will affect the stresses in the vehicle structure differently for different vehicles. Relating the roughness values if we gently apply brake it don’t even feel the stopping in actual wear, but due to worst conditions this causes wear and tear in vehicle structure.

There by driving over the bad category condition often recommended not to stop fully and brake to desired speed and continue moving slowly or at decreased speed to prevent additional heat build-up in braking as well the vehicle wear.

Conclusions

The road roughness is very common issues now-a-days. And familiar to all hence no any critical conclusion on our paper can be established, we have researched only for studying the mathematical impact of roughness on road.

Through this study we conclude that the roughness have very bad impact on traffic and transportation conditions. It impact indirectly on the development of country because transportation is core of development.

We also concluded that some percentage of roughness is allowed as per IRI because of friction on road and wheel of vehicle for appropriate moment.
