## Abstract -

The ability of computers to get creative has come a long way also the exciting role that AI will play is kicking us out of behaving like machines. Since 1990 the enormous growth of internet various technologies has been created to bring users spectacular experiences with more virtual interactions in cyberspace. In this survey, we dive into the metaverse by discussing four important terms and their effect on AI, foundational research, AI for the product team, responsible AI, and AI infrastructure. We then study how blockchain and AI fuse with it through exploring state-of-the-art studies across the metaverse components, digital currencies, AI applications in the virtual world, and blockchain-empowered technologies. We then convey a broad investigation of AI-based methods concerning six-technical terms that have potential for the Metaverse. Subsequently, we will discuss the challenges faced to develop a potential AI. Finally, we will conclude the key contribution of this survey and open some future research directions in AI for the Metaverse.

**Key Words:** Metaverse, Cyberspace, Blockchain

## 1. INTRODUCTION

Metaverse as the latest buzzword has attracted great attention from both industry and academia. Metaverse, a term formed by combining meta and universe, has been introduced as a shared virtual world that is powered by many growing technologies, such as fifth-generation networks and beyond virtual reality, and Artificial Intelligence (AI). Among such technologies, AI has shown the great importance of processing big data to enhance the immersive experience and enable the human-like intelligence of virtual agents. A lot of AI research is focused on understanding the physical world but Metaverse needs an AI that is built around helping people to navigate virtual worlds as well as our physical worlds with augmented reality, -because these worlds will be dynamic and always changing. AI will need to be able to understand the context and learn in the ways that humans do. The Metaverse will consist of immersive worlds that you can create and interact with, with all the visual information that includes one's position in 3D space, one's body language, facial gestures and so on. And this is all from one's first-person perspective.

In this paper, a comprehensive survey of the existing AI-based works from the technical and application

perspectives is conveyed. In a nutshell, the main contributions of this paper are summarized as follows:

- First, we introduce the new tools for the next metaverse.
- We survey, the six technical aspects which have great potential for metaverses, like natural language processing, machine vision, blockchain, networking, digital twin (DT), and neural interface.
- Then we present the preliminaries of the economic system in the metaverse.

Finally, we envision typical challenges and open issues to shape the future metaverse in the next decades.

The rest of this paper is organized as follows. Section 2 introduces the new tools which are used in metaverse followed by Section 3 which describes the adoptions of technical aspects such as natural processing, machine vision, blockchain, networking, DT as well as neural interface. Section 4 mainly describes the characteristic of the ecosystem of the metaverse by comparing it with the conventional economy. Section 5 tells us the challenges which are faced in the metaverse while incorporating new AI tools and machine learning. Section 5 concludes the paper with some future research directions for development.

## 2. New AI tools for the next Metaverse

The kinds of experiences that you will have in the metaverse are beyond what is possible today. It's an immersive version of the internet. Instead of just looking at something on a screen you are going to feel like you are inside it or right there present with another person, and that's going to require advances across a whole range of areas, from new hardware devices to software for building and exploring worlds. And a key to unlocking a lot of these are advances in AI. And there are a few challenges to look upon. First, create a new generation of assistance that will help explore new worlds. Today, A lot of AI research is focused on understanding the physical world. But in Metaverse, we are going to need AI that is built around helping people navigate through virtual worlds as well as physical worlds with augmented reality. And because these worlds can be dynamic and always changing AI is going to need to be able to understand the context and learn in a way that humans do and when we have our glasses on our faces that will be the first time that AI system will be able

to see our perspective. Every time you get a recommendation or search for something or even take a photo on a phone there is a machine learning in the background. Computing is also becoming increasingly contextual instead of this static experience that's the same no matter where you are. The way that we use computers now adapts much more touch to what we are doing and as devices have gotten better at understanding and anticipating at what we want, they've also gotten more useful.

The metaverse will consist of immersive worlds that you can create and interact with, with all the visual information that includes your position in a 3D space your body language, your facial gestures and so on, and this is all from your first-person perspective so you experience it and move through it as you are there. And all that adds up to a lot more input to be processed and a lot more content to be generated. So, there is a need to navigate all this efficiently.

A. Project CAIRaoke-Project CAIRaoke is a full end-to-end neural model for building on device assistance. It combines the approach behind blenderbot with the latest in conversational AI to deliver better dialogue capabilities and from there support true world creation and exploration. We need to advance well beyond the current state of the art for smart assistance. So, working on two areas of AI research to make this possible

1. Egocentric perception- Egocentric perception is about seeing the world from a first-person perspective.
2. New class of generative AI models- Helps to create anything that you can imagine.

B. Project Builderbot- Project builderbot enables you to describe a world and then it will generate aspects of that world for you. As we advance this technology further, we are going to be able to create nuanced worlds to explore and share experiences with just your voice.

## 2. AI for the metaverse: Technical aspect

### A. Natural language processing

Natural language processing (NLP), also refer to as computational linguistics. It consists of a variation of computational models and learning processes to solve practical problems of automatically analysing and understanding human languages. Alongside, the field of NLP thinks about many topics, like conversation design, voice branding, multi-language, and multi-cultu in voice. Moreover, it plays an essential role in the metaverse concerning intelligent virtual assistants(chatbots). NLP is principally in control of qualifying chatbots to recognize tough human conversation in the context of assorted dialects and undertones. Sanctioned by AI, chatbots can answer implied questions and learn from the interaction to

improve the trait of responses. The AI chatbots are established to assist users in Metaverse

### B. Machine Vision

The Foundationthe of metaverse is found to be the centtechnologyies in with machine vision with computer vision and XR.The raw data professed from the visual environments remains captured and administered to infer high-level information, which is then shown to users' overhead mounted devices and others, such as smart glasses and smartphones. Indeed, computer vision allows XR devices to analyse and understand user activities based on visual-based meaningful information. Embodied as avatars in the virtual worlds, the users can freely move in 3D maps and cooperate with virtual objects in the metaverse:

1) Extended Reality: XR is explained as an umbrella term that encloses VR, AR, mixed reality (MR), and everything in their gaps. Although some revolutionary experiences are offered for VR and AR, the same original technologies are fueling the innovation and development of MR. While AR provides the experiences of graphics, video streams, and holograms in the physical world and VR offers viewing experiences in a fully immersive digital world, MR can deliver a transition experience between AR and VR. Along with these reality technologies, human users can experience the metaverse and enjoy diversified services in both the physical and digital worlds. While XR and AI are distinct sectors, they can be combined to reach a fully immersive in the metaverse.

2) Computer Vision: In the last computer vision has been empowered by AI, especially DL with a variety of network architectures to improve the overall accuracy of the visual systems with efficient cost thanks to high-performance graphic processing units. Some fundamental computer vision technologies are the potential to enhance the experience of human users in the metaverse, thus enabling users in the physical world to interact with the virtual environment in the digital world smoothly.

### C. Blockchain

Generally, A Digital register that consists of list of recorded transactions and tracked assets interconnected in a business network by using cryptography is called blockchain. Blockchain can provide immediate, shared, and transparent information stored in an unchangeable and impassable register which can be obtained by only the network members with permission. Tracking order or payments can be done through digital blockchain. In the metaverse, a large amount of data is acquired by VR devices, transmitted over networks, and stored in data centre without any security and privacy protection mechanisms, which can become the sensitive target of cyber-attacks. In the context, blockchain with several

unique features reveals a promising solution for security and privacy issues in the metaverse, especially when it is empowered by AI technologies. Besides, many creative activities and events offered by service providers to users will yield numerous in metaverse objects/items (digital assets) which should be recorded and tracked via transparent transactions with smart contracts in blockchain.

#### D. Networking

The metaverse serves a massive number of users regarding pervasive network access over wireless networks. In the last decade, several innovative technologies have been introduced to improve the overall performance of wireless communication and networking systems, in which AI has been intensively used at multiple layers of network architecture. Real multimedia services and applications in the metaverse usually demand a reliable connection with high throughput and low tenancy to guarantee a basic-level user experience at least. As the requirements of fifth-generation(5G) networks, the peak data rate should be around 10Gbps and the end-to-end delay cannot exceed 10 ms. In this context, ultra-reliable and low latency communications represent the foundation to enable the development of emerging mission-critical applications. Several optimization algorithms have been introduced to achieve uRLLC in 5G networks and beyond, but most of them require high computing resources. ML and DL have shown great potential to effectively handle existing challenging tasks, such as intelligent radio resource allocation, in 5G/6G networks while meeting a very low latency. RL was leveraged to address the resource slicing problem for enhanced mobile broadband(eMBB) and URLLC, in which the complicated patterns of resource allocation and scheduling are formulated to collaboratively learn network states and channel conditions.

#### E. Digital Twins

As a digital representation of digital world entities, a DT can synchronize operational assets, processes, and systems with the real world along with some other regular actions, such as monitoring, visualizing, analysing and predicting. DTs are at the central of where the physical world and thw virtual world will be rejected in the digital representation. With these distinctive properties, DT is found as one the fundamental building sectors of the metaverse and plays as the gateway for users to enter and enjoy services in the virtual world by creating exact replications of reality, including structure and functionality. For example, technicians can maneuver 3D representations of complex systems at multilevel sophistications for a wide spectrum of purposes, such as technical training and commercial customization. Accordingly, DTs allow application developers and service providers to reconstruct virtual replications of machines and processes, in which any kind of physical analysis can be done remotely with AI.

#### F. Neural Interface

Technology is definitely enriching the world around us by enhancing the human experience and fully filling gap between reality and virtual world in the metaverse. In this context, the most immersive popular interface to interactive with virtual work is a VR headset with a controller. Many technology companies currently pay attention to neural interfaces, so-called brain machine interfaces (BMIs) or brain computer interfaces (BCI), that go beyond VR devices. The BMIs help to nearly clean the borderline between human and wearable devices. Many BMIs detect neural signals using external electrodes or optical sensors that adhere to the skull and other parts of the human body.

### 3. Preliminaries of Economic System in Metaverse

A blend virtual reality, augmented reality and sensorial tech and spatial computing, the metaverse promises to give us new experiences from our couches and cubicles. But the metaverse is not just a gaming space, sci-fi dream come true. Nor it is a limited tech companies-it is an entirely new economy.

- Digital creation is the foundation of metaverse. The creation process is similar to the material production in the physical world. Number of creators decide the development of economy.
- Digital Asset has the hidden property, which is the precondition of the trade.
- Digital market is the fundamental place in which avatars can trade to have income like in the physical world.
- Digital currency is the media in metaverse with which the avatars can finish the trade and exchange.

### 4. Preliminaries of economic system in Metaverse

The economy is the fundamental component of metaverse. For the more idealistic perspective, metaverse should ne interoperable such that users can trade virtual items like clothes or cars from one platform to another. Firstly, as depicted in Fig--- we shall describe metaverse economic system according to the mainstream games and existing research works. Metaverse economic system is composed of four parts: digital creation, digital asset, digital market, and digital currency.

- Digital Creation is the foundation of metaverse. The creation progress is similar to material production in th physical world. The development of the economy of the metaverse is decided by the number of creators.

- Digital asset has the hidden property, which is the precondition of trade. For instance, in the FPS game counter-strike: Global offensive, players can equip their weapons with all kinds of 'skins' since that shows the asset attributes the 'skins' since the 'skins' can be exchanged, traded or brought at the platforms.

- Digital Market is the fundamental place in which avatars can trade to have the income like the physical world.

- Digital currency is the media in the metaverse with which the avatars can finish the trade and exchange.

The difference between the economy of metaverse and the conventional economy can be summarised as follows:

- In metaverse, identify determines value instead of the undifferentiated labour in conventional economy.

- The marginal benefits will increase in metaverse instead of diminishing marginal benefits of production in the physical world.

- The marginal costs of products will decrease, comparing with the physical world.

- Transaction cost in metaverse tend to zero, which will incur frequent transactions.

## 5. Challenges faced in Metaverse

A lot of AI work has been focused on text when you have a clearly defined syntax on a finite set of input word and a lot of easily available training data predicting how a sentence might end can be relatively straightforward. But if you have only 10 or 20 percent of an image predicting what the complete image will show is lot more difficult and figuring out what's seen in the video will come next is another step change in complexity. So now imagine going beyond the video to fully immersive experience.

What will it take for AI to accurately interpret and predict the kind of interactions that will happen in the metaverse where people are moving in between physical and virtual spaces including all kinds of new worlds.

The main way to approach this is by working on self-supervised learning and before (SSL) most AI systems were trained with supervised learnings and that means that you feed them lots of label data say hundred thousand images of cats and explicitly tell them this is a cat this isn't a cat until they recognize the patterns but this is a cat this isn't a cat until they recognize the patterns but this wasn't enough to produce systems that can really understand the world.

So, SSL is still developing, but is going to be an important tool in metaverse because the complexity and diversity of

the environments that people will experience in AR ad VR will be too great to be captured with labelled data sets.

Traditional computer vision techniques also aren't enough to support that real sense of presence and interaction that will define the metaverse

## 6. Conclusion

Artificial Intelligence and Blockchain technologies are needed in metaverse to help people navigate virtual worlds as well as physical worlds with augmented reality. For example, metaverse built an AI and blockchain to create a digital virtual world where one can navigate safely and freely in social and economic activities that overpasses the limit of real world.

By surveying, most of the metaverse projects limit users to explore, own, and customize things in virtual world. The most related works across metaverse components, digital currencies, AI technologies and applications in virtual world, and blockchain-empowered technologies I wish to offer a thoughtful review from experts from both the academia and industries.
